#### Abstract

Radical cyclizations of acylsilanes with radicalphilic pendant introduced on silicon proceeded in a tandem fashion to give spiro products containing a cyclic silyl ether skeleton. Because the alkoxysilyl group can be replaced with a hydroxy group through oxidation, the spiro silyl ethers can be converted into diols. In the case with a radical intermediate carrying 2-oxa-3-sila-6-heptenyl skeleton, products derived from 1,7-endo cyclization were obtained in good yields. © 2004 Elsevier Ltd. All rights reserved.

## 1. Introduction

Radical reactions are now widely used as important tools to construct carbon-carbon bonds. ${ }^{1}$ Among various radical reactions, radical additions to carbonyl generate alkoxy radicals that are prone to undergo $\beta$-scission to regenerate the carbonyl functionality. ${ }^{2}$ Yet this seemingly deleterious property can be manipulated to yield ring-expansion ${ }^{3,4}$ and acylation ${ }^{4-7}$ products. The cyclized alkoxy radicals can also be trapped intermolecularly or intramolecularly by hydrogen, ${ }^{8}$ phosphorous, ${ }^{9}$ boron ${ }^{10}$ and tin. ${ }^{11,12}$

Several years ago, we initiated a study of intramolecular radical cyclizations of acylsilanes (Scheme 1). ${ }^{13}$ In this type of cyclizations, radical $\mathbf{1}$ adds intramolecularly to the carbonyl of the acylsilane functionality ${ }^{14}$ to give a $\beta$-silyl substituted alkoxy radical 2. A facile radical-Brook

[^0]rearrangement ${ }^{15,16}$ occurs to afford an $\alpha$-silyloxy radical 3 . In this fashion, the radical carbonyl cyclization reaction can also be driven irreversibly towards ring formation. Depending on the reaction conditions ${ }^{13 c}$ and structural features ${ }^{13 \mathrm{~b}, \mathrm{~d}, \mathrm{f}, \mathrm{j}}$ the intermediate $\alpha$-silyloxy radical 3 can be converted to different products. One possibility (Scheme 2) involves the design of a radicalphile tethered to the silicon atom in such a way that the $\alpha$-silyloxy radical can undergo further cyclization. ${ }^{13 f}$ The alkoxy silane moiety in the resulting silacycles can be considered as a hydroxy group equivalent. ${ }^{17}$ Through oxidative hydrolysis, the silacycles can be opened to give diols. Now we wish to report the full investigation of this approach.

## 2. Results and discussion

As shown in Scheme 3, we choose to synthesize acylsilanes 8 and 9 . These acylsilanes contain allyl and homoallyl group attached on silicon. The strategy developed by Brook ${ }^{18}$ and Corey ${ }^{19}$ was used in the synthesis. We first prepared 2 -silyl-1,3-dithianes 5a (83\%), 5b (64\%) and 5c (68\%) from the silylation of 1,3-dithiane (4) with the corresponding chlorosilanes. However when we used the same method for the preparation of dithiane $\mathbf{5 d}$, small amount of double
bond positional isomerization product was always present and difficult to remove. This was probably caused by the presence of small amount of hydrochloric acid in chloro-dimethyl(3-methyl-3-butenyl)silane. We therefore switched to use an in situ generation method for the preparation of the chlorosilane under a slightly basic condition. ${ }^{20}$ The Grignard reagent prepared from 4-bromo-2-methylbutene in THF was treated with chlorodimethyl(dimethylamino)silane followed by the addition of acetyl chloride. To the chlorodimethyl(3-methyl-3-butenyl)silane solution thus prepared was added the anion generated from 1,3-dithiane to afford pure 2-silyldithiane 5d in $38 \%$ without the formation of its double bond positional isomer.

The 2-silyl-1,3-dithianes were then alkylated with 1,4dibromobutane or 1,5-dibromopentane to afford bromides 6 and 7. Due to the presence of nucleophilic sulfur atoms in the molecule, the bromides are not stable. Although these bromides can be isolated and purified, it is best to hydrolyze the dithiane moiety once the crude bromides are obtained. In the case of the hydrolysis of $\mathbf{6 a}, \mathbf{6 c}, \mathbf{6 d}, 7 \mathbf{c}$, and $\mathbf{7 d}$, ceric ammonium nitrate (CAN) in wet methanol or acetonitrile ${ }^{21}$ was used as the reagent to give acylsilane 8a, 8c, 8d, 9c, and 9d. Iodobenzene bistrifluoroacetate ${ }^{22}$ was used in the hydrolysis of $\mathbf{6 b}, \mathbf{7 a}$, and $\mathbf{7 b}$ to give $\mathbf{8 b}, \mathbf{9 a}$, and $\mathbf{9 b}$,
respectively. The yields for the preparation of acylsilanes $\mathbf{8}$ are lower. This probably reflects the lower stability of the corresponding bromides 6 because in these compounds intramolecular attack of sulfur at the bromo-substituted carbon goes through a favored six-membered ring transition state. In contrast, the homologous bromides 7 contain one more methylene unit and the intramolecular nucleophilic attack by sulfur is more difficult.

The radical cyclization of acylsilane 8a (Scheme 4) was performed by slow addition ( 1 h ) of a benzene solution of tributyltin hydride ( 1.2 equiv) and AIBN ( 0.05 equiv) to a solution of $\mathbf{8 a}$ in refluxing benzene. The concentration with respect to $8 \mathbf{a}$ was 0.05 M . Although there may be four possible products $\mathbf{1 0}-\mathbf{1 3}$, acylsilane $\mathbf{1 0}$, derived from hydrogen abstraction of the initial radical 14, was not observed. This is expected, because radical 1,5-cyclizations of acylsilanes are very fast processes, and straight reduction products are generally not observed. ${ }^{13 \mathrm{~h}, \mathrm{i}}$ Cyclopentyl ether 11 derived from hydrogen abstraction of $\alpha$-silyloxy radical $\mathbf{1 5}$ was observed in $8 \%$ by GC analysis. For the purpose of GC comparison, an authentic sample of ether 11 was prepared from the silylation of cyclopentyl alcohol with allyldimethylsilyl chloride. Radical intermediate $\mathbf{1 5}$ can undergo endo- and exo-cyclization to give spiro silyl ethers 12 and 13, respectively. However, due to the volatility of these silyl ethers, we were only able to isolate the major product $\mathbf{1 2}$ in $46 \%$ yield. We believe some portion of $\mathbf{1 2}$ was lost during concentration. As mentioned earlier, the $\mathrm{C}-\mathrm{Si}$ bond of the alkoxysilyl group can be oxidatively cleaved to result in the replacement of the silyl group with a hydroxy group. ${ }^{17}$ Therefore, we decided to treat the crude cyclization product mixture directly with hydrogen peroxide and potassium hydrogen carbonate in a mixture of methanol

13

Scheme 4.
and THF. ${ }^{23}$ In this way, we isolated $38 \%$ of diol 16 and $20 \%$ of diol 17 . Since diols $\mathbf{1 6}$ and $\mathbf{1 7}$ must be derived from silyl ethers 12 and $\mathbf{1 3}$, respectively, this result showed that the endo-cyclization mode is the preferred process for the cyclization of $\alpha$-silyloxy radical 15 . The ratio of the yields of the two diols, $\mathbf{1 6} / \mathbf{1 7}=1.9 / 1$, then reflects the endolexo cyclization rate ratio of radical 15.

In the cyclization of 5-hexenyl radical it is well-known that 5-exo cyclization is preferred over 6-endo cyclization. ${ }^{1}$ In contrast, it was found that the replacement of C-3 of 5hexenyl radical with a silicon atom directed the cyclization to 6-endo cyclization almost exclusively. ${ }^{24}$ This preference is actually derived from the diminished 5-endo cyclization rate of the $\beta$-dimethylsilyl substituted radical. ${ }^{24 a}$ It was proposed by Wilt et al. ${ }^{24 a}$ that this phenomenon was due to the longer $\mathrm{Si}-\mathrm{C}$ bond and the preferred ground state conformation making the radical more difficult to approach the internal carbon of the olefin. Our cyclization belongs to a 2-oxa-3-sila-5-hexenyl radical system that is rarely found in the literature. The cyclization results of acylsilane 8a indicate that the presence of the silicon atom in this system also affects the mode of ring closure in favor of 6-endo cyclization albeit in a lower endolexo ratio comparing with the 3 -sila-5-hexenyl radical system. Although there is no adequate information in the literature to estimate the effect of the conformation of the silyloxy substituted radical, it can be speculated that the shorter $\mathrm{C}-\mathrm{O}$ and $\mathrm{Si}-\mathrm{O}$ bonds have important contribution influencing the endolexo cyclization ratio of 2-oxa-3-sila-5-hexenyl radical.

Similarly, the reaction of acylsilane 9a (Scheme 5) with tributyltin hydride at a concentration of 0.05 M gave a mixture of straight reduction product 18, monocyclic product 19, and two tandem cyclization products 20 and 21. Direct treatment of the crude cyclization mixture under the oxidation conditions stated above afforded diols 22 and

1) $\mathrm{Bu}_{3} \mathrm{SnH}$

Scheme 5.

23 in 55 and $25 \%$ yields, respectively. Gas chromatographic analysis of the crude cyclization mixture showed the straight reduction product 18 was present in about $7 \%$, and the monocyclic product 19 was present in about $5 \%$. For the purpose of comparison, authentic sample of $\mathbf{1 8}$ was isolated in $51 \%$ yield by performing the cyclization reaction at a more concentrated condition of 0.5 M . The silyl ether 19 was prepared from the reaction of cyclohexanol with allyldimethylsilyl chloride.

For the cyclization of acylsilane $9 \mathbf{9}$, the ratio of endo/exo cyclizations of the intermediate $\alpha$-silyloxy substituted radical extrapolated from the ratio of diols $\mathbf{2 2} / \mathbf{2 3}$ is 2.2/1. This endolexo cyclization ratio is about the same as in the case of the cyclization of acylsilane 8a. Therefore, the regioselectivity of the second ring formation is not strongly influenced by the pre-existing five- or six-membered ring. In the cyclization of $9 \mathbf{a}$, more straight reduction product was obtained. This reflects the slower 1,6-cyclization rate for acylsilanes as observed previously. ${ }^{13 i}$

With a homoallyl group attached to the silicon atom, the two-step radical cyclization-oxidation sequences performed on acylsilanes $\mathbf{8 b}$ and $\mathbf{9 b}$ (Scheme 6) gave diols 24 (67\%) and 26 (78\%), respectively, as the major products. Small amount of diol 25 (3\%) was isolated for the reaction of acylsilane 8b. For the homologous acylsilane 9b, diol 27 was not detected. These results indicate that the 2 -oxa- $3-$ sila-6-heptenyl radical intermediates 28 undergo 1,7-endo cyclization in preference. In the case of acylsilane $9 \mathbf{9 b}, \mathrm{GC}$ analysis of the crude radical cyclization product indicated the presence of $10 \%$ of straight reduction product and $12 \%$ of monocyclic silyl ether. Since the amount of monocyclic product is not much different from those obtained in the case of $8 \mathbf{a}$ and $9 \mathbf{a}$, the 1,7-endo cyclization appears to be quite efficient. Previously, a similar 2,4-dioxa-3-sila-6-heptenyl radical system has also been reported by Myers, Gin and Rogers to give 1,7-endo cyclization predominantly. ${ }^{25}$

We also studied the cyclization of acylsilane $\mathbf{8 c}$ (Scheme 6) having 2-methylallyl substituent on silicon. The methyl group attached on the internal carbon of the olefin directed the radical cyclization of $\mathbf{8 c}$ to afford the spiro silyl ether $\mathbf{3 0}$ in $74 \%$ yield as the only product. We did not detect the presence of monocyclic ether $\mathbf{3 1}$ or acylsilane $\mathbf{3 2}$. Apparently the methyl group on the allyl moiety retarded the attack of the radical appreciably such that the 5-exo cyclization mode was completely suppressed. ${ }^{26}$ In addition, the 6 -endo cyclization led to the formation of a more stabilized tertiary radical. This factor may contribute an acceleration effect that makes this tandem cyclization so efficient.

In comparison, the homologous acylsilane 9c under our standard radical cyclization condition gave $23 \%$ of the tandem cyclization product 33. Again, 6-endo cyclization of the second cyclization step was the predominate process. Analysis of the crude cyclization mixture via ${ }^{1} \mathrm{H}$ NMR revealed the presence of monocyclic product 34 and straight reduction product 35 . The ratio of $\mathbf{3 3 / 3 4 / 3 5}$ determined by NMR integration was $87 / 8 / 5$. The low yield of the spiro product 33 was due to the volatility and the extensive chromatographic processes for its purification. When the

Scheme 6.
crude product of the cyclization of $\mathbf{9 c}$ was directly oxidized under the Tamao oxidation condition, ${ }^{23}$ we were able to obtain the diol 36 in $62 \%$ yield. The formation of small amount of monocyclic silyl ether 34 in this system seems to indicate that the cyclization rate of the intermediate cyclohexyl radical is slightly slower than the corresponding cyclopentyl radical as in the case of acylsilane 8c. We suspect that the allylic methyl group may exhibit repulsive interaction with the $\mathrm{C}(3)$-methylene unit of the cyclohexyl group in the transition state (Fig. 1) of the second cyclization and thus slows down the rate.

Figure 1. The proposed 1,6-endo cyclization transition state of the (2methylallyl)silyloxy substituted cyclohexyl radical.

With a 3-methyl-3-butenyl group attached on silicon, the cyclizations of acylsilanes $8 \mathbf{d}$ and $9 \mathbf{d}$ gave exclusively 7 -endo cyclization product for the second cyclization step. In the case of acylsilane 8d, spiro silyl ether $\mathbf{3 7}$ was isolated in $69 \%$ yield in addition to $7 \%$ of monocyclic product 38. Analysis of the crude product by ${ }^{1} \mathrm{H}$ NMR showed that straight reduction product 39 was not formed. The ratio of spiro silyl ether 37 and monocyclic silyl ether 38 in the crude product was $9 / 1(\mathbf{3 7 / 3 8})$. The reaction of acylsilane $\mathbf{9 d}$ with tributyltin hydride gave a 74/10/9 crude mixture of spiro silyl ether 40, monocyclic silyl ether 41 and straight reduction product $\mathbf{4 2}$, respectively. The spiro silyl ether $\mathbf{4 0}$ was isolated in $40 \%$ through silica gel column chromatography in addition to $6 \%$ of monocyclic product 41 and $7 \%$ of straight reduction product 42 . The presence of $\mathbf{4 2}$ reflected the slower rate of the initial 1,6-cyclization as described above. The lower ratio of spiro product 40 and monocyclic product 41 ( $74 / 10$ by NMR) also showed that the pre-existing six-membered ring might influence the second 7 -endo cyclization.

In summary, we have demonstrated that by introducing radicalphilic pendant on silicon, the radical cyclizations of acylsilanes can proceed in a tandem fashion. Because the alkoxysilyl group can be replaced with a hydroxy group through oxidation, the final cyclization products can be converted to give diols. In the case with a radical intermediate carrying 2-oxa-3-sila-6-heptenyl skeleton, products derived from 1,7-endo cyclization were obtained in good yields.

Melting points are uncorrected. ${ }^{1} \mathrm{H}$ NMR spectra were recorded at 200,300 or $400 \mathrm{MHz} ;{ }^{13} \mathrm{C}$ NMR spectra were recorded at 50,75 or 100 MHz . Tetramethysilane ( $\delta=$ $0 \mathrm{ppm})$ or $\mathrm{CHCl}_{3}(\delta=7.24 \mathrm{ppm})$ were used as internal standards and $\mathrm{CDCl}_{3}$ was used as the solvent. Benzene and THF were distilled from sodium benzophenone ketyl under $\mathrm{N}_{2}$. Diisopropylamine and acetonitrile were dried with $\mathrm{CaH}_{2}$ and distilled. The benzene used for cyclization reactions was deoxygenated by passing a gentle stream of argon through for 0.5 h before use. All reactions were performed under a blanket of $\mathrm{N}_{2}$ or Ar. Lobar LiChroprep Si $60(40-63 \mu \mathrm{~m})$ pre-packed columns purchased from Merck were used for medium pressure liquid chromatography (MPLC). Gas chromatography was performed on a Shimadzu GC-8A apparatus with TCD using a $3.3 \mathrm{~mm} \times$ 2 m column of $10 \%$ SE-30 on Chromosorb W (AWDMCS), 80-100 mesh, and hydrogen as carrier gas.

 (5d). A mixture of $0.358 \mathrm{~g}(14.9 \mathrm{mmol})$ of magnesium turnings and a few crystals of iodine in 1 mL of dry THF was stirred under argon until the iodine color disappeared. A solution of $1.38 \mathrm{~mL}(11.1 \mathrm{mmol})$ of 4-bromo-2-methyl-1butene in 10 mL of dry THF was added to the mixture over a period of 25 min and stirred for another 15 min . The Grignard reagent prepared above was added dropwise over a period of 15 min to a cooled $\left(0^{\circ} \mathrm{C}\right)$ solution of 1.2 mL ( 6.93 mmol ) of chlorodimethyl(dimethylamino)silane in 8 mL of dry THF. The reaction mixture was stirred for another 10 min at $0^{\circ} \mathrm{C}$ followed by the addition of a solution of $0.50 \mathrm{~mL}(6.9 \mathrm{mmol})$ of acetyl chloride in 7 mL of dry THF over a period of 20 min at the same temperature. The resulting mixture was stirred for another 2.5 h at $0^{\circ} \mathrm{C}$ to furnish a solution of dimethyl(3-methyl-3-buten-1-yl)silyl chloride. To another solution of $1.42 \mathrm{~g}(11.9 \mathrm{mmol})$ of $1,3-$ dithiane in 13 mL of dry THF cooled in an ice-water bath was added dropwise over 20 min a 1.5 N solution of butyllithium in hexane $(9.40 \mathrm{~mL}, 14.1 \mathrm{mmol})$. This anion solution was then added to the silyl chloride solutionprepared above at $0^{\circ} \mathrm{C}$ over a period of 20 min , and the reaction mixture was stirred for 1.5 h at room temperature. The resulting mixture was poured into 20 mL of sat. ammonium chloride solution and extracted with 100 mL of ether. The organic layer was washed with water $(100 \mathrm{~mL} \times$ 2), brine $(100 \mathrm{~mL})$, dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo to give 2.31 g of a yellow residue. ### 3.3. General procedure for intramolecular radical cyclizations and oxidations: cyclization of 8a followed by oxidation. 1-(2-Hydroxy-1-methyl)ethylcyclopentanol (17)

To a refluxing solution of $150 \mathrm{mg}(0.57 \mathrm{mmol})$ of $\mathbf{8 a}$ in 2.5 mL of benzene was added via syringe pump over 2.5 ha solution of $0.18 \mathrm{~mL}(0.68 \mathrm{mmol})$ of tributyltin hydride and $5.0 \mathrm{mg}(0.031 \mathrm{mmol})$ of AIBN in 6 mL of benzene. The resulting solution was heated for another 2 h and then
cooled to room temperature. Gas chromatographic analysis (oven tempertature $=130^{\circ} \mathrm{C}$; flow rate $=28 \mathrm{~mL} / \mathrm{min}$ ) of the reaction mixture showed the presence of $11\left(t_{\mathrm{R}}=6.4 \mathrm{~min}\right)$, $\mathbf{1 3}\left(t_{\mathrm{R}}=7.3 \mathrm{~min}\right)$, and $\mathbf{1 2}\left(t_{\mathrm{R}}=8.1 \mathrm{~min}\right)$ in a ratio of 1:3:8.3, respectively. The reaction mixture was concentrated in vacuo. The residue was mixed with $626 \mathrm{mg}(6.26 \mathrm{mmol})$ of potassium bicarbonate, 0.68 mL ( 23 mmol ) of hydrogen peroxide, 8 mL of methanol, and 8 mL of THF. The resulting mixture was stirred at $66^{\circ} \mathrm{C}$ for 19 h and then partitioned between 50 mL of dichloromethane and 30 mL of water. The aqueous phase was extracted with dichloromethane ( 50 mL ), and the combined organic layers were dried $\left(\mathrm{MgSO}_{4}\right)$, and concentrated in vacuo. The residue was chromatographed over silica gel (eluted with hexane/ethyl acetate, $7 / 3,6 / 4,4 / 6$ in sequence) to give $16 \mathrm{mg}(20 \%)$ of the less polar 17 as a colorless oil: IR (neat) 3431 (br) $\mathrm{cm}^{-1}$; ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}, 200 \mathrm{MHz}\right) \delta 0.98(\mathrm{~d}, J=7 \mathrm{~Hz}, 3 \mathrm{H}), 1.38-$ $1.95(\mathrm{~m}, 9 \mathrm{H}), 3.00(\mathrm{br} \mathrm{s}, 2 \mathrm{H}), 3.62(\mathrm{dd}, J=10.5,5 \mathrm{~Hz}, 1 \mathrm{H})$, $3.84(\mathrm{dd}, J=10.5,4 \mathrm{~Hz}, 1 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}, 50 \mathrm{MHz}\right) \delta$ 12.8, 23.5, 23.8, 37.2, 39.2, 42.3, 66.9, 86.1; HRMS calcd for $\mathrm{C}_{8} \mathrm{H}_{16} \mathrm{O}_{2} \mathrm{~m} / \mathrm{z}$ 144.1150, found 144.1140.
