**The transcription of the  $\alpha$ 1-acid glycoprotein gene is induced by inflammatory cytokines and glucocorticoids. C/EBP $\beta$  is a major transcription factor involved in the induction of the *agp* gene by some cytokines. In this report, we have identified a novel transcriptional intermediary factor, TIF1 $\beta$ , which could enhance the transcription of the *agp* gene by the glucocorticoid receptor (GR) and C/EBP $\beta$ . TIF1 $\beta$  belongs to a subgroup of RING (really interesting new gene) finger proteins that contain a RING finger preceding two B box-type fingers and a putative coiled-coil domain (RBCC domain). Immunoprecipitation experiments showed that the interaction between GR and TIF1 $\beta$  is ligand independent. The overexpression of the TIF1 $\beta$  gene enhances GR-regulated expression in a ligand- and glucocorticoid-responsive element (GRE)-dependent manner. TIF1 $\beta$  can also augment C/EBP $\beta$ -mediated activity on wild-type and GRE-mutated *agp* genes, but this augmentation is diminished when all three C/EBP $\beta$ -binding elements are mutated. Functional and biochemical characterizations indicated that the bZIP domain of C/EBP $\beta$  and the RBCC domain, plant homeodomain finger, and bromodomain of TIF1 $\beta$  are crucial for the interactions of these proteins. Taken together, these results suggest that TIF1 $\beta$  serves as a converging mediator of signal transduction pathways of glucocorticoids and some inflammatory cytokines.**

The acute-phase reaction to inflammatory stimuli is accompanied by an increase in a variety of serum proteins, collectively named acute-phase proteins. The synthesis of these proteins is regulated by glucocorticoids and inflammatory cytokines, such as interleukin 1 (IL-1), IL-6, and tumor necrosis factor  $\alpha$  (5–7, 62). C/EBP $\beta$  was initially identified as the key transcription factor involved in the regulation of the  $\alpha$ 1-acid glycoprotein (AGP) gene during the acute-phase response (termed AGP/EBP) (18). C/EBP $\beta$  was also shown to be involved in the regulation of a number of other genes, such as those for IL-6 and albumin (termed NF-IL-6, LAP, IL-6DBP, or CRP2) (2, 14, 20, 49, 61). In addition to C/EBP $\beta$ -binding motifs, a glucocorticoid-responsive element (GRE) also exists between –120 and –107 in the 5'-flanking region of the *agp* gene (8, 18). Previous reports showed that maximal induction of the *agp* gene by glucocorticoids also requires another C/EBP $\beta$ -binding element located downstream of GRE (34, 50, 60). The synergistic interaction between cytokines and glucocorticoids has been attributed to protein-protein interactions between C/EBP $\beta$  and the glucocorticoid receptor (GR) (45).

GR belongs to a family of nuclear receptors that function as ligand-dependent transcription factors (9, 48). Transcriptional activation of target genes by nuclear receptors is mediated by two activation regions, AF1, located in the N terminus, and AF2, located in the C terminus of the hormone-binding domain of the receptor. GR-mediated transcription is promoter dependent and cell specific (for a review, see reference 24).

Results from studies of transcriptional interference or squelching between AF1 and AF2 of steroid receptors suggested the existence of coactivators or transcriptional interme-

diary factors which interact specifically with the AF1 and AF2 domains (3, 39, 55). Recent studies have led to the identification of several proteins that interact with nuclear receptors in a ligand-dependent manner and play essential roles in mediating their transcriptional activities. These proteins include RIP140 (15), TIF1 (36), Trip1/SUG1 (38, 59), SRC-1/p160 (26, 31, 47), TIF2/Grip1 (29, 58), ARA70 (63), and CBP/p300 (16, 27, 31). Several of these factors showed markedly different affinities for various nuclear receptors (56, 59). CBP and p300 are large nuclear proteins and have been demonstrated to interact functionally with a number of sequence-specific transcriptional activators (for a review, see reference 30). Previous data indicated that competition for limiting amounts of CBP may account for many of the inhibitory actions of both GR and the retinoic acid receptor on AP1 activation (31).

Genes for two related TIF1 proteins, TIF1 $\alpha$  and TIF1 $\beta$ , have been cloned and shown to be members of the RING (really interesting new gene) finger family (for reviews, see references 12 and 52). The RING finger motif can be defined simply as Cys3-His-Cys4, a new class of the zinc finger. At least 80 members of the RING finger family have been identified. Many members, including the tumor suppressor BRCA-1 (42), the oncogene product Mel18 (32), and the mediator of the tumor necrosis factor receptor, TRAF2 (51), have been implicated as being in control of cell growth, cell differentiation, and development. The functions of these RING fingers remain to be defined, although some reports have suggested that they are the interface for protein-protein interactions (4, 10).

To delineate the mechanisms of transcriptional regulation of the *agp* gene by C/EBP $\beta$ , we have initiated studies on proteins that interact with C/EBP $\beta$  by purifying them using a number of procedures, including anti-C/EBP $\beta$  antibody immunoaffinity chromatography (40, 41). In this report, we present results on the identification and characterization of the roles of TIF1 $\beta$  in the activation of the *agp* gene. These results indicate that the

enhancement of GR or C/EBP $\beta$  activity by TIF1 $\beta$  occurs through direct protein-protein interactions.

#### MATERIALS AND METHODS

**Plasmids and constructs.** The EST clone containing partial human TIF1 $\beta$  cDNA (from nucleotides 1882 to 2673) was obtained from Research Genetics. An 0.8-kb DNA fragment insert isolated from the plasmid was used as a probe for screening the day-16 mouse embryo cDNA library (Novagen). A cDNA clone with a 2.8-kb insert containing the complete open reading frame of TIF1 $\beta$  was obtained. Mammalian expression plasmids were constructed by cloning the following TIF1 $\beta$  fragments into cytomegalovirus (CMV) expression vector pcDNA3 (Invitrogen): the full-length *EcoRI-HindIII* fragment (pcDNA3-TIF1 $\beta$ ), and *EcoRI-SacI* fragment (residues 1 to 563), an *EcoRI-PvuII* fragment (residues 1 to 372), and a fragment resulting from *BamHI* deletion (residues 80 to 383 deleted) of the full-length *EcoRI-HindIII* fragment. An *SfiI-HindIII* fragment (residues 14 to 834), a *BamHI* fragment (residues 80 to 383), a *BamHI-SacI* fragment (residues 383 to 563), and a *BamHI-HindIII* fragment (residues 383 to 834) were cloned into the pGEX-1 vector (Pharmacia) for the production of glutathione *S*-transferase (GST) fusion proteins. The full-length *EcoRI* fragment of C/EBP $\beta$ , an N-terminal *NcoI* fragment (amino acids 21 to 151 [C/EBP $\beta$ -N]), or a C-terminal *NcoI-HindIII* fragment (amino acids 151 to 296 [C/EBP $\beta$ -C]) was ligated to the pRSET vector (Invitrogen) for recombinant protein production.

Other plasmid constructs, such as pCMV-C/EBP $\beta$ , rat AGP (wild type [WT])-CAT, AGP (C mutant)-CAT, AGP (D mutant)-CAT, AGP (E mutant)-CAT, AGP (CDE mutant)-CAT, and AGP (GRE mutant)-CAT, were as described previously (40, 59). Briefly, the plasmids were obtained by ligation of the wild-type or mutant (see below) rat *agp* gene promoter sequence from -736 to +1 to the chloramphenicol acetyltransferase (CAT) reporter gene. The C, D, E, and GRE mutants correspond to serial 3-base substitutions at positions -74 to -72 (ACA to GTG), -96 to -94 (CAA to TGG), -106 to -104 (AGA to GAG), and -118 to -116 (ACA to GTG), respectively. pMMTV-CAT is the mouse mammary tumor virus long terminal repeat ligated to the CAT reporter gene. The mammalian cell expression vector (pRSV-hGR) and recombinant baculovirus containing GR were kindly provided by M.-J. Tsai of Baylor College of Medicine. pRSV-CREB and pCMV-PKAc were obtained from Susan Taylor.

**Recombinant proteins and antibodies.** Human TIF1 $\beta$  (from nucleotide 1882 to 2673) was cloned into the pRSET vector and expressed in *Escherichia coli* BL21(DE3)(pLysS). This recombinant protein was purified on a nickel column and used for rabbit immunization. Monoclonal and polyclonal antibodies to C/EBP $\beta$  were as described previously (18). Anti-GR antibody was purchased from Santa Cruz Biotech.

**Cell cultures, transient transfection, and CAT assay.** BHK, HeLa, and P388D1 cells were cultured in Iscove's modified Dulbecco's medium supplemented with 10% fetal calf serum. DNA transfection was performed by the calcium phosphate precipitation method. BHK cells were grown in 6- or 3.5-cm-diameter petri dishes to 30 to 40% confluence. The amounts of CAT reporter plasmid DNA and expression plasmid DNA used in each experiment are described in the figure legends. pcDNA3 plasmid DNA was used to adjust the total amount of DNA for each transfection to be equal. pCMV/SEAP (Tropix) (0.5  $\mu$ g) was included in each transfection as an internal control for transfection efficiency. During the 24-h posttransfection period, the cells were placed in fresh medium and, in some experiments, induced with 1  $\mu$ M dexamethasone (water soluble; Sigma). Cells were harvested 24 h later and extracted with 100  $\mu$ l of 0.25 M Tris-HCl (pH 7.8). The acetylated forms of chloramphenicol were separated by thin-layer chromatography and quantified with an image analyzer (BAS 1000; Fuji). All transfection experiments were repeated two to four times.

**Preparation of whole-cell extracts, immunoprecipitation, and Western blotting.** Whole-cell extracts from P388D1 cells were prepared by lysing the cells with buffer containing 25 mM HEPES (pH 7.6), 0.3 M NaCl, 1.5 mM MgCl<sub>2</sub>, 0.2 mM EDTA, 0.5% Nonidet P-40 (NP-40), and 0.5 mM dithiothreitol (DTT). For immunoprecipitation analysis, 1 mg of whole-cell extracts was precleared with preimmune serum and protein A-Sepharose in 0.5 ml of immunoprecipitation buffer (25 mM HEPES [pH 7.6], 0.25 M NaCl, 1 mM EDTA, 0.1% NP-40, 0.5 mM DTT, 6% glycerol) at 4°C for 2 h. The precleared supernatants were incubated with 5  $\mu$ g of anti-TIF1 $\beta$  or anti-C/EBP $\beta$  antibody and protein A-Sepharose in the presence or absence of 1  $\mu$ M dexamethasone at 4°C for 90 min. After extensive washes, the protein complex was dissolved in sodium dodecyl sulfate (SDS) loading buffer and subjected to SDS-polyacrylamide gel electrophoresis (PAGE). The separated polypeptides were blotted onto a Hybond-C membrane (Amersham) and probed with anti-TIF1 $\beta$ , anti-C/EBP $\beta$ , or anti-GR antibody. The results were detected with an enhanced chemiluminescence kit (Amersham).

**Protein-protein interaction assay.** Glutathione-Sepharose 8A beads (Pharmacia) were mixed with 3  $\mu$ g of wild-type or deletion mutant recombinant GST-TIF1 $\beta$  fusion protein or GST only in 500  $\mu$ l of phosphate-buffered saline containing 1% Triton X-100 on a rotary shaker for 20 min at room temperature. The beads were washed three times with phosphate-buffered saline, combined with 100 ng of recombinant full-length C/EBP $\beta$ , truncated C/EBP $\beta$ -N, or truncated C/EBP $\beta$ -C in a final volume of 500  $\mu$ l of binding buffer (25 mM HEPES [pH 7.6], 0.25 M NaCl, 1 mM EDTA, 0.1% NP-40, 0.5 mM DTT, 6% glycerol), and

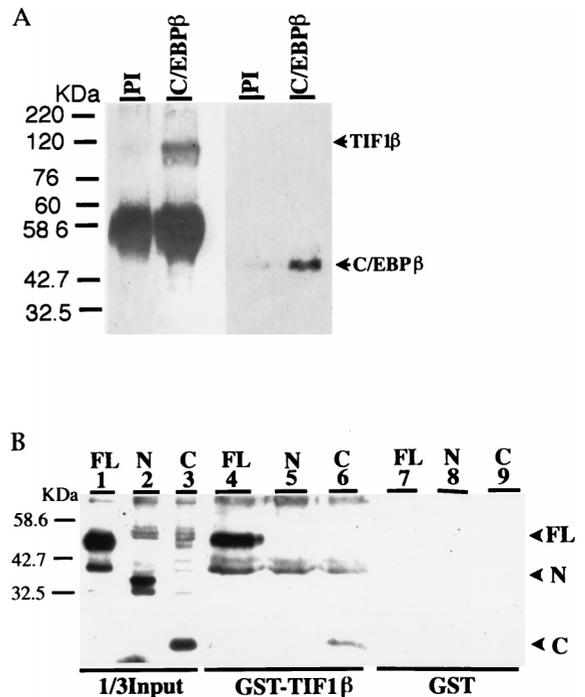

FIG. 1. Protein-protein interactions between C/EBP $\beta$  and TIF1 $\beta$ . (A) P388D1 whole-cell extracts were immunoprecipitated with anti-C/EBP $\beta$  polyclonal antibody (C/EBP $\beta$ ) or preimmune serum (PI). The precipitated proteins were subjected to SDS-PAGE followed by Western blotting with anti-C/EBP $\beta$  monoclonal or anti-TIF1 $\beta$  polyclonal antibodies. (B) Several recombinant C/EBP $\beta$  constructs were incubated with glutathione bead-immobilized GST-TIF1 $\beta$  (lanes 4 to 6) or GST (lanes 7 to 9). After extensive washes, the protein complexes were subjected to SDS-PAGE and immunoblotted with anti-C/EBP $\beta$  antibody. Lanes 1 to 3 represent direct loading of different recombinant C/EBP $\beta$  constructs. FL, N, and C represent full-length C/EBP $\beta$ , C/EBP $\beta$ -N, and C/EBP $\beta$ -C, which are described in Materials and Methods.

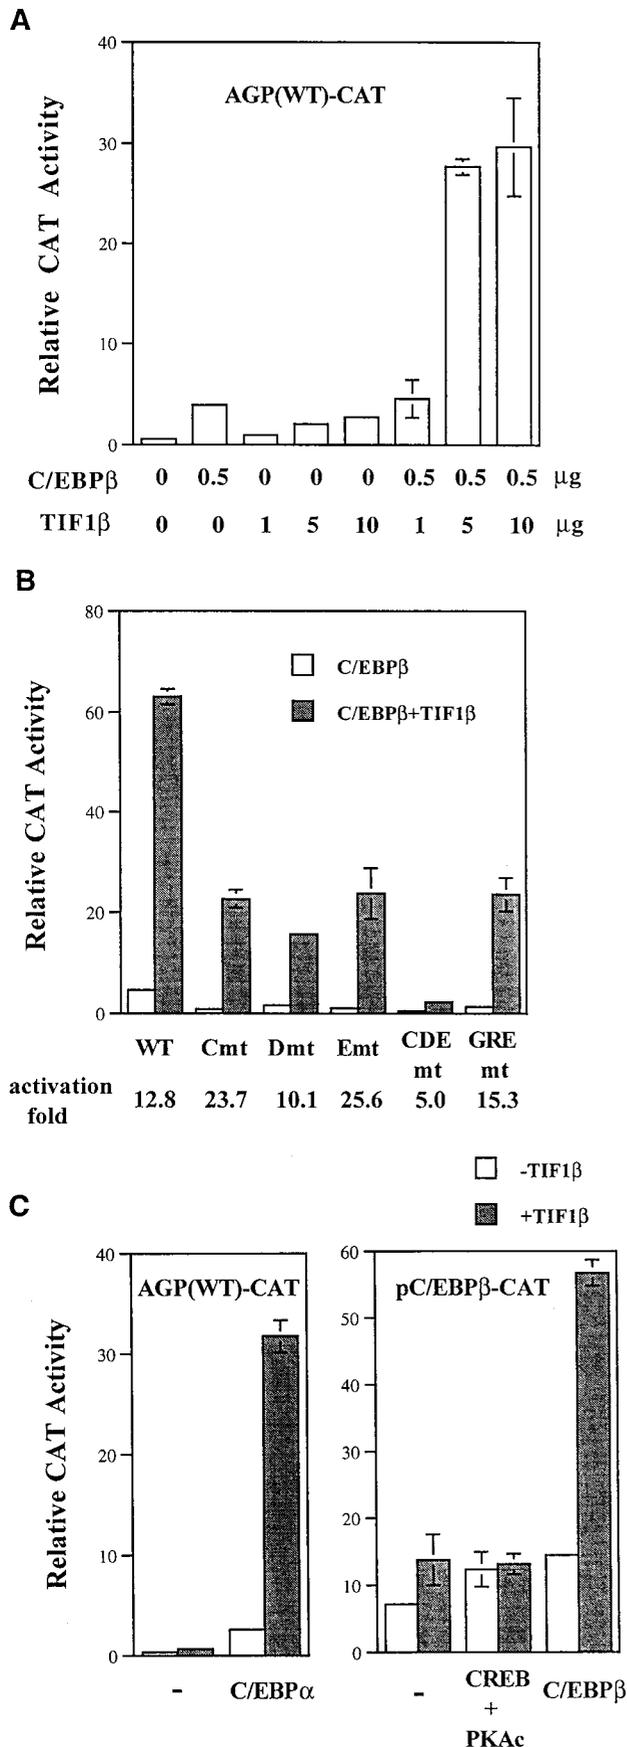

incubated on a rotary shaker for 2 h at 4°C. The beads were washed three times with binding buffer, and the bound proteins were subjected to SDS-PAGE and Western blot analysis.

#### RESULTS

##### Isolation and characterization of cDNA clones for TIF1 $\beta$ .

The RING finger protein family consists of members found in animals, plants, and viruses, but the function of the RING finger domain remains to be defined. By comparison with sequences of RING finger domains similar to those of inhibitors of apoptosis or RING-1, a number of human EST clones carrying putative RING finger domains were identified. Sequence analysis revealed that one of these clones, containing an 0.8-kb insert, was highly homologous to a mouse protein, TIF1 $\beta$  (37). Rabbit antibodies were generated by use of a recombinant protein derived from the EST clone. In serendipitous Western blot experiments for identifying C/EBP $\beta$ -interacting proteins, we used a rabbit anti-TIF1 $\beta$  antibody as a control. Surprisingly, it reacted with a protein of ~100 kDa that appeared in the eluent of the anti-C/EBP $\beta$  immunoaffinity column (data not shown). This observation prompted us to study the possible physical and functional interactions between TIF1 $\beta$  and C/EBP $\beta$ . Using the 0.8-kb DNA fragment as a probe to screen the mouse cDNA library, a 2.8-kb cDNA clone that could encode a protein of 834 amino acids was obtained.

TIF1 $\beta$  and TIF1 $\alpha$  are strongly homologous in the N- and C-terminal regions. The N-terminal region is a RING finger preceding two B box-type fingers and a putative coiled-coil

domain (RBCC motif) (36). The C-terminal region consists of a plant homeodomain (PHD) finger followed by a bromodomain (36).

TIF1 $\beta$  appears to be widely expressed, since Northern blotting reveals a major 3-kb TIF1 $\beta$  transcript in all human tissues (data not shown). The subcellular localization of TIF1 $\beta$  was then determined by indirect immunofluorescence, which showed granular staining of TIF1 $\beta$  only in the nucleoplasm and not in the nucleolus (data not shown).

**TIF1 $\beta$  stimulates the C/EBP $\beta$ -mediated activation of the *agp* gene.** The physical interaction of C/EBP $\beta$  and TIF1 $\beta$  was examined by an immunoprecipitation assay. P388D1 is a mouse macrophage cell line which expresses C/EBP $\beta$  constitutively. Anti-C/EBP $\beta$  antibody can bring down TIF1 $\beta$  in P388D1 whole-cell extracts (Fig. 1A). Direct protein-protein interactions were studied by pull-down assays with GST-TIF1 $\beta$  (full length) and both full-length C/EBP $\beta$  and truncated forms of C/EBP $\beta$ , C/EBP $\beta$ -N and C/EBP $\beta$ -C (Fig. 1B). The results showed that the bZIP domain of C/EBP $\beta$  (i.e., C/EBP $\beta$ -C) is sufficient for its direct interaction with TIF1 $\beta$ .

To characterize the functional role of TIF1 $\beta$  in the activation of the *agp* gene by C/EBP $\beta$ , we performed cotransfection experiments. TIF1 $\beta$  augmented the activation of the *agp* gene by C/EBP $\beta$  in a dose-dependent manner (Fig. 2A). To further elucidate the roles of C/EBP $\beta$ -binding motifs in the activation effect between C/EBP $\beta$  and TIF1 $\beta$ , we performed cotransfection assays with reporters containing mutated C/EBP $\beta$ -binding motifs (C, D, E, and CDE mutants). Compared to the results obtained with the wild-type reporter gene, there was stimulation of C/EBP $\beta$  activity by TIF1 $\beta$  with the C-, D-, or E-site-mutated reporter gene (13-fold for the wild type and 26-, 10-, and 24-fold for the C, D, and E mutants, respectively). Induction by these factors was dramatically reduced when a reporter containing mutations of all three C/EBP $\beta$ -binding sites (i.e., the CDE mutant) was tested (Fig. 2B). Transactivation of the GRE-mutated *agp* gene by C/EBP $\beta$  and TIF1 $\beta$  was comparable to that of the wild-type gene (Fig. 2B). Thus, the augmentation effect of TIF1 $\beta$  on the activation of the C/EBP $\beta$  gene is exclusively C/EBP $\beta$ -binding motif dependent, and GR is apparently not required.

To further assess the activation specificity of TIF1 $\beta$  and other factors, we conducted transient transfection assays with expression vectors for C/EBP $\alpha$ , CREB, and TIF1 $\beta$ . As shown in Fig. 2C, left panel, TIF1 $\beta$  also augmented the C/EBP $\alpha$ -mediated transactivation of the *agp* gene. The pC/EBP $\beta$ -CAT reporter contains the promoter from the *c-ebp $\beta$*  gene (nucleotides -390 to +82) (17). It has been reported that there are C/EBP- and CREB-responsive elements in the regulatory region of *c-ebp $\beta$*  (17, 44). TIF1 $\beta$  potentiated C/EBP $\beta$  activity but

FIG. 2. Stimulation of C/EBP $\beta$ -mediated gene activation by TIF1 $\beta$ . (A) BHK cells were cotransfected with 2  $\mu$ g of AGP (WT)-CAT, 0.5  $\mu$ g of pCMV-C/EBP $\beta$  (C/EBP $\beta$ ), and increasing amounts of pcDNA3-TIF1 $\beta$  (TIF1 $\beta$ ) (1, 5, and 10  $\mu$ g). (B) In 3.5-cm-diameter petri dishes, BHK cells were cotransfected with 0.5  $\mu$ g of AGP (WT)-CAT, AGP (C mutant)-CAT, AGP (D mutant)-CAT, AGP (E mutant)-CAT, AGP (CDE mutant)-CAT, or AGP (GRE mutant)-CAT and 0.1  $\mu$ g of pCMV-C/EBP $\beta$  with or without 2  $\mu$ g of pcDNA3-TIF1 $\beta$ . The data represent the average activity of two independent duplicate experiments. The fold induction by TIF1 $\beta$  is indicated below the panel. mt, mutant. (C) (Left panel) In 3.5-cm-diameter petri dishes, BHK cells were cotransfected with 0.5  $\mu$ g of AGP (WT)-CAT and 0.05  $\mu$ g of pCMV-C/EBP $\alpha$  in the presence or absence of 2  $\mu$ g of pcDNA3-TIF1 $\beta$ . (Right panel) BHK cells were transfected with 0.25  $\mu$ g of pC/EBP $\beta$ -CAT, and 0.1  $\mu$ g of pCMV-C/EBP $\beta$  or both 0.1  $\mu$ g of pRSV-CREB and 0.1  $\mu$ g of pCMV-PKAc in the absence or presence of 2  $\mu$ g of pcDNA3-TIF1 $\beta$ . Error bars indicate standard deviations. -, pcDNA3 vector control.

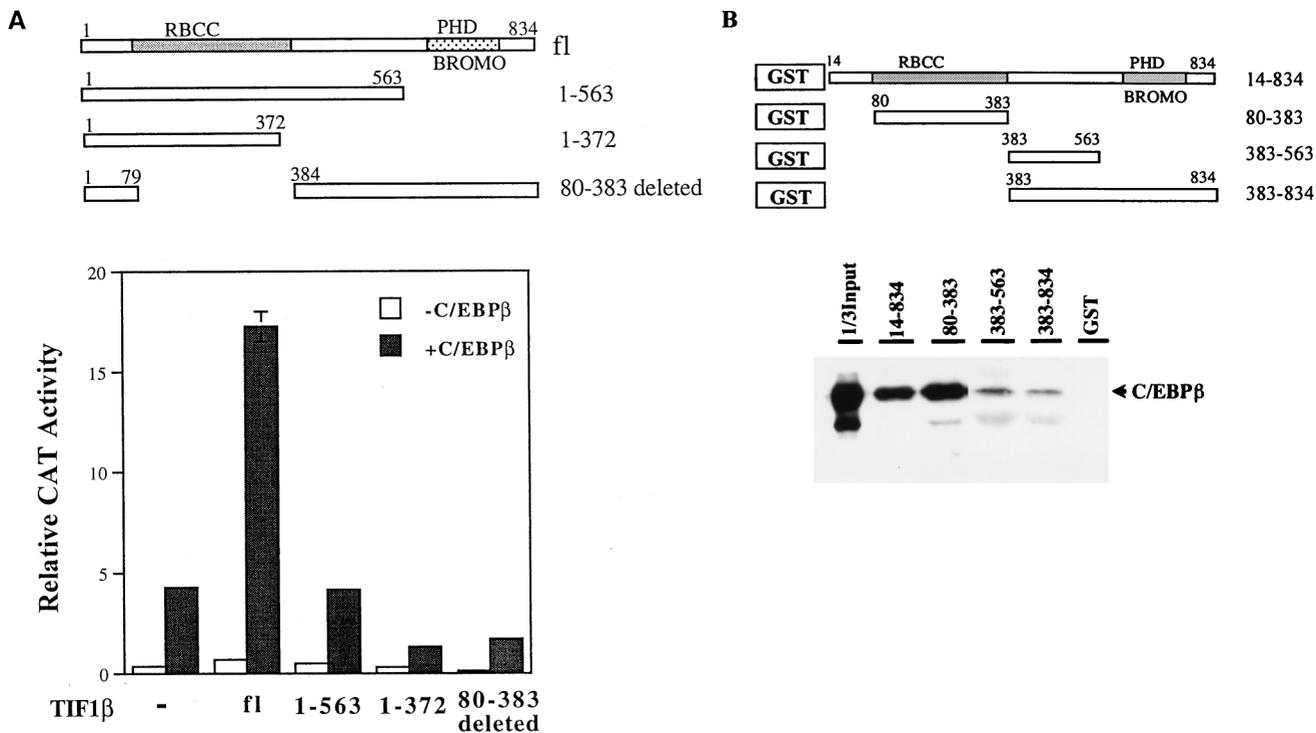

FIG. 3. Functional and biochemical characterization of C/EBP $\beta$ -interacting domains of TIF1 $\beta$ . (A) (Upper panel) Schematic representation of several TIF1 $\beta$  expression vectors; numbers denote amino acid positions. (Lower panel) Transient transfection assays. BHK cells (in 3.5-cm-diameter petri dishes) were transfected with 0.5  $\mu$ g of AGP (WT)-CAT, 0.1  $\mu$ g of pCMV-C/EBP $\beta$ , and 2  $\mu$ g of pcDNA3-TIF1 $\beta$  (full length [fl] or from amino acid 1 to 563 or 1 to 372, or full length but with amino acids 80 to 383 deleted). (B) (Upper panel) Schematic representation of several GST-TIF1 $\beta$  fusion proteins. (Lower panel) Protein pull-down assay. Glutathione bead-immobilized recombinant GST-TIF1 $\beta$  (fl or from amino acid 80 to 383, 383 to 563, or 383 to 834) incubated with full-length recombinant C/EBP $\beta$  (100 ng). After extensive washes, the protein complex was analyzed by immunoblotting with anti-C/EBP $\beta$  antibody. -, pcDNA3 vector control.

not CREB activity in the *c-ebp* $\beta$  gene promoter (Fig. 2C, right panel).

To define the regions of TIF1 $\beta$  that could interact with C/EBP $\beta$  physically and functionally, we constructed mammalian cell expression vectors and prepared recombinant GST fusion proteins of various deletion mutants of TIF1 $\beta$  (Fig. 3A and B, upper panels). Mutants of TIF1 $\beta$  with either the PHD finger and the bromodomain deleted (amino acids 1 to 563) or the RBCC domain deleted (amino acids 80 to 383 deleted) failed to potentiate the activation of the *agp* gene by C/EBP $\beta$  (Fig. 3A, lower panel). Physical interaction experiments with recombinant proteins derived from C/EBP $\beta$  and deletion mutants of TIF1 $\beta$  indicated that the RBCC domain of TIF1 $\beta$  was sufficient to interact with C/EBP $\beta$  (Fig. 3B, lower panel). The region of amino acids 383 to 563 seemed to interact weakly with C/EBP $\beta$ . Taken together, these results suggest that TIF1 $\beta$  interacts with C/EBP $\beta$  through the RBCC domain and enhances C/EBP $\beta$  transcriptional activity through the PHD finger and the bromodomain.

**TIF1 $\beta$  enhances the transcriptional activity of GR.** TIF1 $\alpha$  was identified as a protein that interacts directly with the ligand-binding domains of several nuclear receptors in a ligand- and AF2-dependent manner both in vivo and in vitro. It was suggested that TIF1 $\alpha$  mediates the transcriptional activation of the target gene by the AF2 domain of nuclear receptors (36). TIF1 $\alpha$  and TIF1 $\beta$  share highly conserved domains. To further investigate the role of TIF1 $\beta$  in nuclear receptor-mediated transactivation of target gene expression, we performed transient transfection assays. As shown in Fig. 4, in the presence of exogenous GR and dexamethasone, TIF1 $\beta$  stimulated the transcription of mouse mammary tumor virus and the *agp*

promoter in a dose-dependent manner. TIF1 $\beta$  did not augment the transcriptional activity of GR in the absence of dexamethasone (data not shown).

To determine the molecular basis of target gene activation by TIF1 $\beta$  and GR, we conducted an analysis of the interaction between TIF1 $\beta$  and GR by an immunoprecipitation assay. Polyclonal antibody to TIF1 $\beta$  but not preimmune serum immunoprecipitated GR from P388D1 whole-cell extracts in the absence or presence of dexamethasone (Fig. 5A); the anti-GR antibody detected two isoforms, 95 and 90 kDa). This result indicates that TIF1 $\beta$  and GR coexist in a complex. Direct protein-protein interactions were examined by an immunoprecipitation assay with GST-TIF1 $\beta$  fusion protein and recombinant GR. TIF1 $\beta$  interacted with GR in the absence or presence of dexamethasone (Fig. 5B).

Previous studies indicated that maximal induction of the *agp* gene by glucocorticoid requires the downstream C/EBP $\beta$ -binding sequences (34, 50, 60). To further study the TIF1 $\beta$ -mediated GR induction of the *agp* gene, we performed transfection assays using *agp* promoters containing mutated C/EBP $\beta$ -binding sites or mutated GRE. As indicated by the previous results, the activation of the *agp* gene by TIF1 $\beta$  and GR was observed only in the presence of dexamethasone (Fig. 6). Reporters containing mutated C/EBP $\beta$ -binding elements (namely, C, D, and E mutants) remained responsive to TIF1 $\beta$  and GR. In contrast, the reporter containing mutated GRE was unresponsive to TIF1 $\beta$  and GR (Fig. 6). The activation of the *agp* gene by TIF1 $\beta$  alone in the presence of dexamethasone was likely due to the effect of endogenous GR. These results show that the transcriptional activation of the *agp* gene by TIF1 $\beta$  and GR is dependent on GRE but independent of C/EBP $\beta$ -binding motifs.

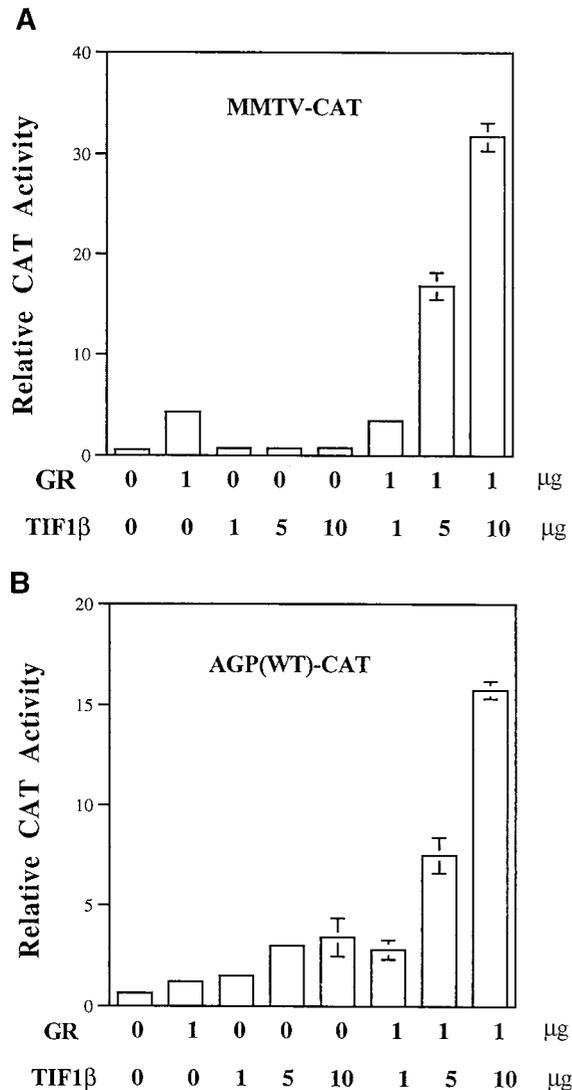

FIG. 4. TIF1 $\beta$  potentiates GR-activated gene expression. (A) HeLa cells were transiently transfected with 2  $\mu$ g of pMMTV-CAT reporter plasmid, 1  $\mu$ g of pRSV-hGR (GR), and increasing amounts of pCDNA3-TIF1 $\beta$  (TIF1 $\beta$ ) (1, 5, and 10  $\mu$ g). Each assay was done in the presence of 1  $\mu$ M dexamethasone. (B) BHK cells were transiently transfected with 2  $\mu$ g of AGP (WT)-CAT reporter plasmid. Other plasmids and conditions of treatment are as described for panel A. Relative CAT activity normalized with an internal control represents an average of two independent duplicate experiments. Error bars indicate standard deviations.

We further examined the effect of TIF1 $\beta$  on the *agp* gene by cotransfecting pRSV-GR and pCMV-C/EBP $\beta$  simultaneously. As shown in Fig. 7, the net effect of the transactivation of the *agp* gene by cotransfection of pCMV-C/EBP $\beta$ , pRSV-GR, and pCMV-TIF1 $\beta$  seemed to be the result of pRSV-GR plus pCMV-TIF1 $\beta$ . Taken together, these results suggest that there is no additive or synergistic activation of the *agp* gene by the overexpression of GR, TIF1 $\beta$ , and C/EBP $\beta$  under these experimental conditions.

## DISCUSSION

TIF1 $\beta$  was originally identified as a protein that interacts directly with two chromosomal proteins, mHP1 $\alpha$  and mMOD1 (37). In this report, TIF1 $\beta$  was identified as a coactivator for

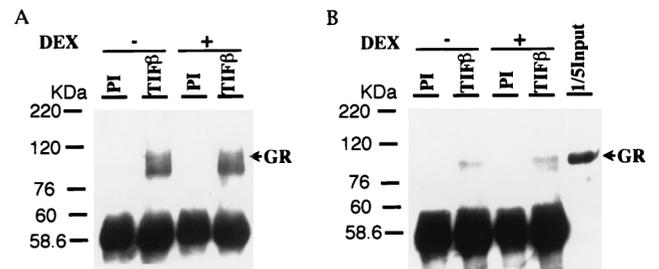

FIG. 5. Protein-protein interactions between GR and TIF1 $\beta$ . (A) Immunoprecipitation of GR by anti-TIF1 $\beta$  antibody. P388D1 whole-cell extracts were immunoprecipitated with anti-TIF1 $\beta$  or control (PI) antibody in the presence (+) or absence (-) of 1  $\mu$ M dexamethasone (DEX) and subjected to SDS-PAGE and Western blotting with anti-GR polyclonal antibody. (B) Recombinant GST-TIF1 $\beta$  was incubated with recombinant GR in the presence (+) or absence (-) of 1  $\mu$ M dexamethasone and then immunoprecipitated with anti-TIF1 $\beta$  antibody or preimmune serum. After extensive washes, the protein complex was analyzed by Western blotting with anti-GR antibody. Recombinant GR used for the interaction assay (1/5 input) was included as a control.

C/EBP $\beta$  and GR in the activation of the *agp* gene. The specificity of TIF1 $\beta$  for GR or C/EBP $\beta$  was demonstrated by transfection assays with wild-type or mutant reporter plasmids containing GRE and/or C/EBP $\beta$ -binding elements. Direct protein-protein interactions between TIF1 $\beta$  and GR or C/EBP $\beta$  were apparently responsible for the activation of the *agp* gene by these proteins. These results suggest that TIF1 $\beta$  may act as an integrator or coactivator for both glucocorticoid and cytokine signaling pathways leading to the activation of C/EBP $\beta$ . The identification of TIF1 $\beta$  as a coactivator provides further clues about the mechanisms of transactivation by GR and C/EBP $\beta$  and the regulation of their target genes, such as acute-phase response genes.

The competition for a common coactivator, CBP, by AP-1 and the nuclear receptor provides an example of how genes that contain either an AP-1- or a nuclear receptor-binding site could be regulated (31). However, a more complex pattern of regulation was observed for genes containing composite response elements. One GRE and three C/EBP $\beta$ -binding sites are located in the upstream regulatory region of the *agp* gene. The regulation of this gene by interactions between TIF1 $\beta$ , GR, and C/EBP $\beta$  seems to be complex and depends on the steady-state levels of these factors. When pRSV-GR, pCMV-C/EBP $\beta$ , and pCMV-TIF1 $\beta$  were cotransfected into cells, no apparent changes in the transactivation of the *agp* gene were seen compared to those seen with pRSV-GR and pCMV-TIF1 $\beta$  (Fig. 7). In fact, the slight decrease in activation observed could have been attributed to competition between C/EBP $\beta$  and GR for TIF1 $\beta$ .

Results from the deletion analysis indicated that the RBCC domain and the PHD domain-bromodomain are essential for the function of TIF1 $\beta$ . The RBCC domain is the C/EBP $\beta$ -interacting domain. Although the actual functional significance of these domains is unknown, it is currently assumed that they are involved in protein-protein interactions. The RBCC motif has been found in the N-terminal part of several putative transcriptional factors, ribonucleoproteins, and proto-oncogene products, including PML, RFP, RPT-1, SS-A/Ro, XNF7, and PWA33 (for a review, see reference 21). Three RBCC domain-containing proteins, PML, RFP, and TIF1 $\alpha$ , have been identified in the context of fusion oncoproteins resulting from chromosomal translocations. The RBCC domain is fused to truncated products of other genes (23, 36, 54). Mutations in the RBCC domain of PML prevent PML nuclear body formation (11). Many PHD finger-containing proteins have been

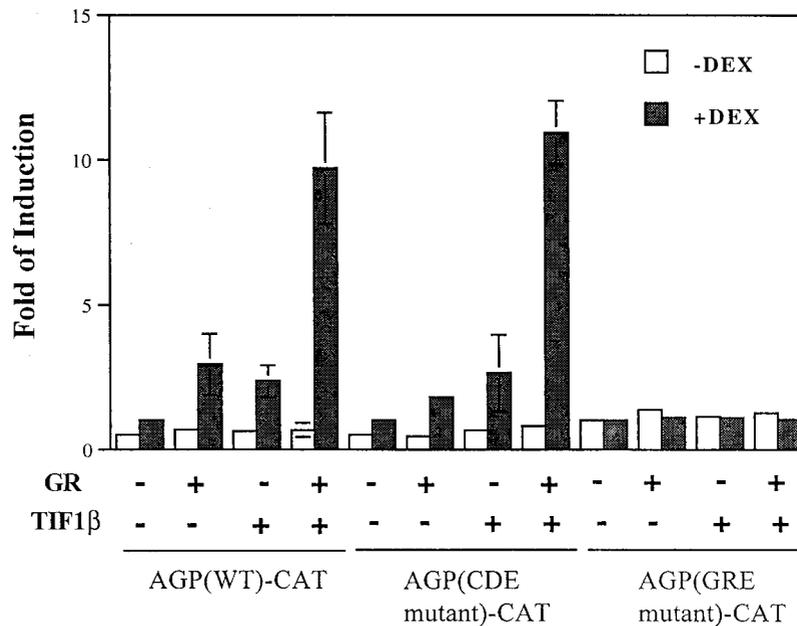

FIG. 6. GRE-dependent and C/EBP $\beta$ -binding-element-independent augmentation of the activation of AGP-CAT by GR and TIF1 $\beta$ . AGP (WT)-CAT, AGP (CDE mutant)-CAT, or AGP (GRE mutant)-CAT was used as a reporter (see Materials and Methods). In 3.5-cm-diameter petri dishes, BHK cells were cotransfected with one reporter plasmid (1  $\mu$ g) and 0.5  $\mu$ g of pRSV-hGR (GR), 5  $\mu$ g of pcDNA3-TIF1 $\beta$  (TIF1 $\beta$ ), or both in the presence or absence of 1  $\mu$ M dexamethasone (DEX). The fold induction for each experiment is shown. The values are the averages of at least two independent experiments. Error bars indicate standard deviations.

implicated in interactions between chromosomal proteins (1). These include products of the *Drosophila* genes *trithorax* and *polycomblike*. It is interesting to note that bromodomains are found in the adaptor proteins p300, CBP, and GCN5, as well as in SWI/SNF2 (13, 30, 35). These proteins reside in large mul-

tiprotein complexes. Thus, the overall structure of TIF1 $\beta$  implies that it activates gene transcription by taking part in the formation of multiprotein complexes.

A TIF1 $\beta$ -related protein, TIF1 $\alpha$ , was found to interact with several nuclear hormone receptors. TIF1 $\alpha$  contains a nuclear receptor-binding motif, LXXLL (28, 37). However, there is no motif resembling LXXLL in the TIF1 $\beta$  sequence. Inhibition of RXR $\alpha$  activity was observed as a result of ectopic expression of TIF1 $\alpha$  in the transient transfection assays. The RBCC domain-containing protein PML exerts a very powerful enhancing effect on the transactivating properties of several steroid hormone receptors (25). It is likely that a specific functional interaction exists between coactivators and nuclear receptors. The activation effect of TIF1 $\alpha$  or TIF1 $\beta$  on GR- or RXR $\alpha$ -induced gene expression, respectively, remains to be studied.

In addition to GR and C/EBP $\beta$ , TIF1 $\beta$  has been reported to interact with the transcriptional silencing domain of the *Drosophila* Kruppel-related KRAB proteins and to serve as a corepressor (22, 33, 43). The mechanism of repression by TIF1 $\beta$  remains elusive. To test the possibility that TIF1 $\beta$  is a general mediator of various transcriptional factors, we performed cotransfection assays with mammalian cell expression vectors for CREB and the protein kinase A catalytic subunit in the presence of the pC/EBP $\beta$ -CAT reporter. TIF1 $\beta$  could not enhance CREB activity (Fig. 2C). Another member of the C/EBP family, C/EBP $\alpha$ , was also tested, and the results showed that TIF1 $\beta$  could augment the C/EBP $\alpha$ -activated expression of AGP (WT)-CAT (Fig. 2C). Thus, in addition to C/EBP $\beta$ , the transcriptional activity of another member of the C/EBP family may be modulated by TIF1 $\beta$ .

How could TIF1 $\beta$  function as a coactivator? TIF1 $\beta$  seems to be a bifunctional protein involved in the remodeling of the chromatin template in both the repression and the activation of transcription (37). Thus, the interaction between GR and TIF1 $\beta$  or between C/EBP $\beta$  and TIF1 $\beta$  may promote the conversion of a transcriptionally inactive heterochromatin-like

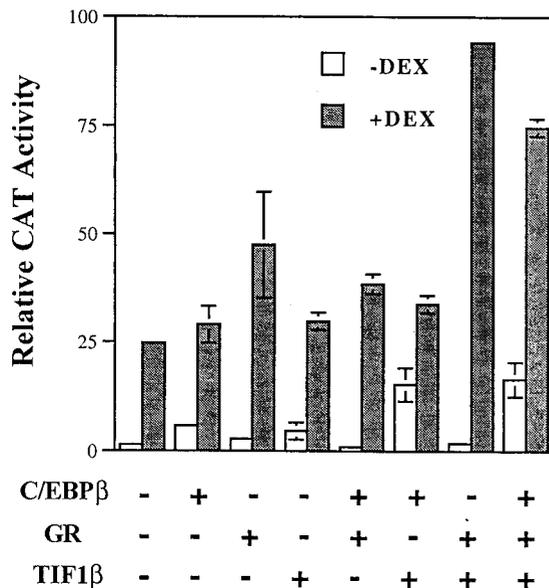

FIG. 7. Activation of the *agp* gene by C/EBP $\beta$ , GR, and TIF1 $\beta$ . BHK cells (grown in 6-cm petri dishes) were transfected with 2  $\mu$ g of AGP (WT)-CAT and 0.5  $\mu$ g of pCMV-C/EBP $\beta$  (C/EBP $\beta$ ), 1  $\mu$ g of pRSV-hGR (GR), or 5  $\mu$ g of pcDNA3-TIF1 $\beta$  (TIF1 $\beta$ ) in various combinations in the absence or presence of 1  $\mu$ M dexamethasone (DEX). Normalized relative CAT activity represents an average of two independent experiments. Error bars indicate standard deviations.

structure to an active euchromatin-like open structure by triggering the release of HP1 and MOD1 (37). We previously identified a nucleolar phosphoprotein, Nopp140, that functions as a mediator between C/EBP $\beta$  and the general transcription factor TFIIB (40). In light of the analogous features shared by the interactions between C/EBP $\beta$  and Nopp140 or TIF1 $\beta$ , we also tested the physical interaction between TIF1 $\beta$  and TFIIB. Our results did not offer conclusive evidence on any physical interaction between TIF1 $\beta$  and TFIIB (data not shown). Thus, the mechanism of activation of the *agp* gene by C/EBP $\beta$  and TIF1 $\beta$  is different from that of C/EBP $\beta$  and Nopp140.

The present results revealed a direct protein-protein interaction between TIF1 $\beta$  and GR and showed that this interaction is ligand independent. However, the functional interaction between GR and TIF1 $\beta$  is ligand dependent. It is speculated that TIF1 $\beta$  may participate in the formation of a coactivator complex to activate target gene expression. CBP has been demonstrated to interact with other nuclear receptor coactivators (SRC-1/ACTR/pCIP family) to form a functional complex and to result in a synergistic response to the nuclear receptors (19, 31, 57). These coactivators have been identified as histone acetyltransferases that remodel chromatin structure to facilitate transcriptional activation (19, 46, 53). Further experiments to identify other TIF1 $\beta$ -interacting proteins may yield important mechanistic insights.

#### ACKNOWLEDGMENTS

This research was supported by grants NSC86-2311-B001-089 and NSC88-2311-B001-114 (to C.-J.C.) and NSC86-2311-B001-094-Y (to S.-C.L.) from the National Science Council.

We thank Susan Taylor, Sophia Tasi, and Ming-Jer Tasi for plasmids and Bertrand Chin-Ming Tan for critical reading of the manuscript.
