#### Abstract

The crystal structures of acetato- $N$-tosylimido-meso-tetraphenylporphyrinatothallium(III), $\mathrm{Tl}(\mathrm{N}-\mathrm{NTs}-\mathrm{tpp})(\mathrm{OAc})$ (1), and acetato- $N$-tosylimido-meso-tetraphenylporphyrinatogallium(III), $\mathrm{Ga}(\mathrm{N}-\mathrm{NTs}-\mathrm{tpp})(\mathrm{OAc})(\mathbf{2})$, were determined. The coordination sphere around the $\mathrm{Tl}^{3+}$ ion is a distorted square-based pyramid in which the apical site is occupied by a chelating bidentate $\mathrm{OAc}^{-}$group, whereas for the $\mathrm{Ga}^{3+}$ ion, it is a distorted trigonal bipyramid with $\mathrm{O}(3), \mathrm{N}(3)$, and $\mathrm{N}(5)$ lying in the equatorial plane. The porphyrin ring in the two complexes is distorted to a large extent. For the $\mathrm{Tl}^{3+}$ complex, the pyrrole ring bonded to the NTs ligand lies in a plane with a dihedral angle of $50.8^{\circ}$ with respect to the 3 N plane, which contains the three pyrrole nitrogens bonded to $\mathrm{Tl}^{3+}$, but for the $\mathrm{Ga}^{3+}$ complex, this angle is found to be only $24.5^{\circ}$. In the former complex, $\mathrm{Tl}^{3+}$ and $\mathrm{N}(5)$ are located on the same side at 1.18 and $1.29 \AA$ from its 3 N plane, but in the latter one, $\mathrm{Ga}^{3+}$ and $\mathrm{N}(5)$ are located on different sides at -0.15 and $1.31 \AA$ from its 3 N plane. The free energy of activation at the coalescence temperature $T_{\mathrm{c}}$ for the intermolecular acetate exchange process in $\mathbf{1}$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ solvent is found to be $\Delta G^{\ddagger}{ }_{171}=36.0 \mathrm{~kJ} / \mathrm{mol}$ through ${ }^{1} \mathrm{H}$ NMR temperature-dependent measurements. In the slow-exchange region, the methyl and carbonyl (CO) carbons of the $\mathrm{OAc}^{-}$group in $\mathbf{1}$ are separately located at $\delta 18.5\left[{ }^{3} J\left(\mathrm{Tl}-{ }^{13} \mathrm{C}\right)=220 \mathrm{~Hz}\right]$ and $176.3\left[{ }^{2} J\left(\mathrm{Tl}-{ }^{13} \mathrm{C}\right)=205 \mathrm{~Hz}\right]$ at $-110{ }^{\circ} \mathrm{C}$.

## Introduction

Metalloporphyrins with a bridged structure between the central metal and one of the four pyrrole nitrogens have drawn much attention because it was proposed that the highly oxidized form of some hemoproteins may contain a ferric porphyrin with an oxygen atom inserted into an $\mathrm{N}-\mathrm{Fe}$ bond. ${ }^{1,2}$ Only bridged metalloporphyrins with metal $-\mathrm{N}-\mathrm{N}$ linkages (metal $=\mathrm{Zn}, \mathrm{Ni}$, $\mathrm{Fe}, \mathrm{Hg})^{3-8}$ have so far been reported. Callot ${ }^{3}$ and Mahy ${ }^{7}$ described the X-ray structure investigation of the metalation of N -tosylamido-meso-tetraphenylporphyrin [ $\mathrm{N}-\mathrm{NHTs}-\mathrm{Htpp}$ ] (NHTs $=$ tosylamido, tpp $=$ dianion of meso-tetraphenylporphyrin, $\mathrm{Ts}=$ tosyl $)^{9}$ leading to mononuclear complexes of

[^0]N -tosylimido-meso-tetraphenylporphyrinatonickel(II) $[\mathrm{Ni}(\mathrm{N}-$ $\mathrm{NTs}-\mathrm{tpp})$ ] ( $\mathrm{NTs}=$ tosylimido) ${ }^{3}$ and chloro- N -tosylimido-meso-tetraphenylporphyrinatoiron(III), $\mathrm{Fe}(\mathrm{N}-\mathrm{NTs}-\mathrm{tpp}$ ) Cl (or $\mathrm{Fe}(\mathrm{TPP})(\mathrm{NTs})(\mathrm{Cl})$, bridged). ${ }^{7}$ The nickel in $\mathrm{Ni}(\mathrm{N}-\mathrm{NTs}-$ tpp $)$ is tetracoordinated to three pyrrole nitrogens and one extra nitrogen atom from the nitrene fragment. The four pyrrole nitrogens are approximately coplanar. The nickel atom lies out of this four-nitrogen mean plane ( 4 N ) by $0.21 \AA$, and the extra nitrogen is also in the same direction with a distance of 0.94 $\AA$. The porphyrin macrocyclic is distorted because of the nitrene insertion and because the perturbed pyrrole ring is oriented at a very large dihedral angle of $40.5^{\circ}$ with respect to the 4 N plane; the other three pyrroles are oriented at quite smaller angles of $1.8^{\circ}, 4.4^{\circ}$, and $9.4^{\circ} .^{3}$
The iron atom in $\mathrm{Fe}(\mathrm{N}-\mathrm{NTs}-$ tpp $) \mathrm{Cl}$ is pentacoordinated, and its coordination geometry is a distorted trigonal bipyramid with an equatorial plane containing three different atoms, $\mathrm{Cl}, \mathrm{N}(\mathrm{Ts})$, and one pyrrole nitrogen. The porphyrin ring is also severely distorted as the pyrrole ring bonded to the NTs ligand orients in a dihedral angle of $29.9^{\circ}$ with the 3 N plane, which contains the three pyrrole nitrogens bonded to the iron. ${ }^{7}$

However, until now there are no X-ray structural data available for the diamagnetic metal ion (M(III)) complexes of N -NHTs-Htpp with coordination number (CN) above 4 (i.e., with $\mathrm{CN} \geq 5$ ). In this paper, we present the results with the replacement of $\mathrm{Ni}(\mathrm{II})$ and Fe (III) with Ga (III) and $\mathrm{Tl}($ III ), respectively. This replacement causes the coordination
number to increase from 4 for $\mathrm{Ni}^{\mathrm{II}}(\mathrm{N}-\mathrm{NTs}-\operatorname{tpp})^{3}$ to 5 for trans-acetato- N -tosylimido-meso-tetraphenylporphyrinatogallium(III) $\mathrm{Ga}(\mathrm{N}-\mathrm{NTs}-\operatorname{tpp})(\mathrm{OAc})(\mathbf{2})$ and from 5 for coordinated complex $\mathrm{Fe}(\mathrm{N}-\mathrm{NTs}-\mathrm{tpp}) \mathrm{Cl}^{7}$ to 6 for cis-acetato- N -tosylimido-meso-tetraphenylporphyrinatothallium(III) $\mathrm{Tl}(\mathrm{N}-$ NTs-tpp)(OAc) (1). It is noted that the ionic radius increases from $0.69 \AA$ for both $\mathrm{Ni}^{2+}$ and $\mathrm{Ga}^{3+}$ to $0.72 \AA$ for $\mathrm{Fe}^{3+}$ and $1.025 \AA$ for $\mathrm{Tl}^{3+} .{ }^{10}$ The relative positions of the $\mathrm{OAc}^{-}$and N -tosyl groups coordinated to the metal atom lead to a cis configuration in $\mathbf{1}$ and a trans configuration in 2 that might depend on the ionic radius of the $\mathrm{Tl}^{3+}$ and $\mathrm{Ga}^{3+}$. According to our previous report, ${ }^{11}$ the ${ }^{13} \mathrm{C}$ chemical shift of the carbonyl carbon of the acetato group in the diamagnetic complexes of $\mathrm{M}($ por $)(\mathrm{OAc})_{n}$ could indicate the axial binding mode. In addition, the ${ }^{13} \mathrm{C}$ chemical shift of the $\beta$-pyrrole carbon $\left(\mathrm{C}_{\beta}\right)$ provides a complementary method for investigating the distortion of the $N$-pyrrole ring via the insertion of the nitrene moiety into the $\mathrm{Tl} \cdots \mathrm{N}$ bond in complex $\mathbf{1}$ and $\mathrm{Ga} \cdots \cdot \mathrm{N}$ bond in complex 2. This paper reports (i) an X-ray structure determination that clearly establishes the $\mathrm{Tl}^{\mathrm{II}}-\mathrm{NTs}-\mathrm{N}$ structure for the $\mathrm{Tl}(\mathrm{N}-$ $\mathrm{NTs}-\operatorname{tpp})(\mathrm{OAc})$ complex and the $\mathrm{Ga}^{\mathrm{III}}-\mathrm{NTs}-\mathrm{N}$ structure for the $\mathrm{Ga}(\mathrm{N}-\mathrm{NTs}-\mathrm{tpp})(\mathrm{OAc})$ complex and (ii) the ${ }^{13} \mathrm{C}$ chemical shifts of the carbonyl carbon and the $\beta$-pyrrole carbon for further demonstration of the carboxylate coordination and the porphyrin macrocycle distortion, respectively. In addition, the ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra of $\mathbf{1}$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ at low temperature are used to investigate the intermolecular apical ligand $\left(\mathrm{OAc}^{-}\right)$exchange process and in turn to determine the free energy of activation at the coalescence temperature, $\Delta G^{\ddagger}{ }_{\mathrm{Tc}}$, for the exchange process.

## Experimental Section

Preparation of $\mathbf{T l}(\mathbf{N}-\mathbf{N T s}-\mathbf{t p p})(\mathbf{O A c})$ (1). Compound N -tosyl-amido-meso-tetraphenylporphyrin $[\mathrm{N}-\mathrm{NHTs}-\mathrm{Htpp}]$ was prepared as described in the literature. ${ }^{3}$ To a solution of $\mathrm{Tl}(\mathrm{OAc})_{3}(45 \mathrm{mg}, 0.118$ mmol ) and $\mathrm{NaOAc}(10 \mathrm{mg}, 0.122 \mathrm{mmol})$ in $\mathrm{CH}_{3} \mathrm{OH}\left(5 \mathrm{~cm}^{3}\right)$ was added N -NHTs $-\mathrm{Htpp}(100 \mathrm{mg}, 0.118 \mathrm{mmol})$ in $\mathrm{CHCl}_{3}\left(20 \mathrm{~cm}^{3}\right)$, and the resulting solution was refluxed for 30 min . After the solution was concentrated, it was dissolved in $\mathrm{CHCl}_{3}$ and collected by filtration. Recrystallization from $\mathrm{CHCl}_{3} / \mathrm{MeOH}$ afforded $\mathbf{1}$ as a purple solid (110 $\mathrm{mg}, 0.105 \mathrm{mmol}, 87.5 \%$ ). Compound $\mathbf{1}$ was dissolved in $\mathrm{CHCl}_{3}$ and layered with MeOH . The purple and parallelpiped shape crystals of $\mathbf{1}$ were obtained for single-crystal X-ray analysis. Tables 1 and 2 summarize the ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR data. MS, $\mathrm{m} / \mathrm{z}$ (assignment, rel intensity): 1045 ([Tl(N-NTs-tpp)(OAc)] $\left.{ }^{+}, 27.70\right), 986$ ([Tl(N-NTstpp $\left.)]^{+}, 31.23\right), 831\left([\mathrm{Tl}(\mathrm{tpp})+\mathrm{N}+\mathrm{H}]^{+}, 69.66\right), 817\left([\mathrm{Tl}(\mathrm{tpp})+\mathrm{H}]^{+}\right.$, 72.23), 614 ( $\left.\mathrm{Htpp}^{+}, 50.68\right), 205\left({ }^{(205} \mathrm{Tl}^{+}, 100\right), 203\left({ }^{203} \mathrm{Tl}^{+}, 85.78\right) . \mathrm{UV} /$ visible spectrum, $\lambda(\mathrm{nm})\left(\epsilon \times 10^{-3}\left(\mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)\right)$ in $\mathrm{CHCl}_{3}: 446$ (22.5), 558 (0.3), 602 (0.9).

Preparation of $\mathbf{G a}(\mathbf{N}-\mathbf{N T s}-\mathbf{t p p})(\mathbf{O A c})$ (2). Free base $\mathrm{N}-\mathrm{NHTs}-$ Htpp ( 150 mg ) and $\mathrm{Ga}_{2} \mathrm{O}_{3}(200 \mathrm{mg})$ were refluxed for 1 h in $30 \mathrm{~cm}^{3}$ of acetic acid containing sodium acetate ( 150 mg ). After removal of the solvent (HOAc) under reduced pressure, the residue was dissolved in $\mathrm{CHCl}_{3}$ and then dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$. After filtration, the filtrate was rotavaped, and recrystallization from $\mathrm{CHCl}_{3} / n$-hexane $[1: 6$ (v/v)] afforded a purple solid of $\mathbf{2}(139.35 \mathrm{mg}, 0.148 \mathrm{mmol}, 86 \%)$. The crystals were grown by diffusion of ether vapor into a $\mathrm{CHCl}_{3}$ solution. Tables 1 and 2 summarize the ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR data. MS, $m / z$ (assignment, rel intensity): $850\left([\mathrm{Ga}(\mathrm{N}-\mathrm{NTs}-\mathrm{tpp})-\mathrm{H}]^{+}, 21.90\right), 696([\mathrm{Ga}(\mathrm{tpp})+$ $\left.\mathrm{N}^{+}, 29.08\right), 681\left([\mathrm{Ga}(\mathrm{tpp})]^{+}, 100\right), 605\left(\left[\mathrm{Ga}(\mathrm{tpp})-\mathrm{C}_{6} \mathrm{H}_{5}+\mathrm{H}\right]^{+}\right.$, 22.63). UV/visible spectrum, $\lambda(\mathrm{nm})\left(\epsilon \times 10^{-3}\left(\mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)\right)$ in $\mathrm{CHCl}_{3}$ : 436 (377), 544 (9.5), 587 (15.1), 635 (3.0).

Spectroscopy. Proton and ${ }^{13} \mathrm{C}$ NMR spectra were recorded using $\mathrm{CDCl}_{3}$ or $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ at 300.00 (400.13 or 599.95 ) and 75.43 (100.61 or

150.87) MHz, respectively, on a Varian VXR-300 Bruker AM-400, or Varian Unity Inova-600 spectrometer. The temperature of the spectrometer probe was calibrated by the shift difference of methanol resonance in the ${ }^{1} \mathrm{H}$ NMR spectrum. ${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$ COSY was used to correlate protons and carbon through one-bond coupling and HMBC (heteronuclear multiple bond coherence) for two- and three-bond proton-carbon coupling.

The positive-ion fast atom bombardment mass spectrum (FAB MS) was obtained in a nitrobenzyl alcohol (NBA) matrix using a JEOL JMS-SX/SX 102A mass spectrometer.

Crystallography. Table 3 presents the crystal data as well as other information for $\mathrm{Tl}(\mathrm{N}-\mathrm{NTs}-\operatorname{tpp})(\mathrm{OAc})(\mathbf{1})$ and $\mathrm{Ga}(\mathrm{N}-\mathrm{NTs}-\operatorname{tpp})(\mathrm{OAc})$ (2). Measurements were taken on a Siemens R 3m/V diffractometer for 1 and on a Siemens SMART CCD diffractometer for 2 using monochromatized Mo $K \alpha$ radiation $(\lambda=0.71073 \AA)$. Empirical absorption corrections were made for $\mathbf{2}$. The structures were solved by direct methods (SHELXTL IRIS for $\mathbf{1}$ and SHELXTL PLUS for 2) and refined by the full-matrix least-squares method. All non-hydrogen atoms were refined with anisotropic thermal parameters, whereas all hydrogen atom positions were calculated using a riding model and were included in the structure factor calculation. Table 4 lists selected bond distances and angles for both complexes.

## Results and Discussion

Molecular Structures of 1 and 2. The skeletal frameworks are illustrated in Figure 1a for the complex $\mathrm{Tl}(\mathrm{N}-\mathrm{NTs}-\mathrm{tpp})$ (OAc) $\cdot 0.75 \mathrm{CHCl}_{3}$ with $P 2_{1} / c$ symmetry and in Figure 1b for $\mathrm{Ga}(\mathrm{N}-\mathrm{NTs}-\mathrm{tpp})(\mathrm{OAc})$ (2) with $P \overline{1}$ symmetry. Their structures are a six-coordinate thallium and a five-coordinate gallium, having three nitrogen atoms of the porphyrins and one extra nitrogen atom of the nitrene fragment in common, but they are different with a chelating bidentate $\mathrm{OAc}^{-}$ligand for $\mathbf{1} \cdot 0.75 \mathrm{CHCl}_{3}$ and a monodentate $\mathrm{OAc}^{-}$ligand for $\mathbf{2}$. In compounds $\mathbf{1}$ and $\mathbf{2}$ it appears that the $N$-tosyl moiety is inserted into $\mathrm{Tl}-\mathrm{N}$ and $\mathrm{Ga}-\mathrm{N}$ bonds of acetato(meso-tetraphenylporphyrinato)thallium(III), $\mathrm{Tl}(\mathrm{tpp})(\mathrm{OAc}),{ }^{11-13}$ and acetato(mesotetraphenylporphyrinato)gallium(III), Ga(tpp)(OAc). ${ }^{11,14}$ The unusual bond distances from Tl (III) and $\mathrm{Ga}(\mathrm{III})$ atoms to the ligand and the angles are summarized in Table 2. Bond distances $(\AA)$ are $\mathrm{Tl}-\mathrm{N}(1)=2.347(7), \mathrm{Tl}-\mathrm{N}(2)=2.152(7), \mathrm{Tl}-\mathrm{N}(3)=$ $2.361(7), \mathrm{Tl}-\mathrm{N}(5)=2.103(7), \mathrm{Tl}-\mathrm{O}(1)=2.401(8), \mathrm{Tl}-\mathrm{O}(2)$ $=2.292(9), \mathrm{O}(1)-\mathrm{C}(21)=1.22(2), \mathrm{O}(2)-\mathrm{C}(21)=1.19(2)$, and $\mathrm{C}(21)-\mathrm{C}(22)=1.50(2) \AA$ for $\mathbf{1} \cdot 0.75 \mathrm{CHCl}_{3}$; they are $\mathrm{Ga}(1)-$ $\mathrm{N}(2)=2.031(3), \mathrm{Ga}(1)-\mathrm{N}(3)=1.911(3), \mathrm{Ga}(1)-\mathrm{N}(4)=$ $2.031(3), \mathrm{Ga}(1)-\mathrm{N}(5)=1.946(3), \mathrm{Ga}(1)-\mathrm{O}(3)=1.868(3)$, $\mathrm{O}(3)-\mathrm{C}(52)=1.260(5), \mathrm{O}(4)-\mathrm{C}(52)=1.218(5)$, and $\mathrm{C}(52)-$ $C(53)=1.515(6) \AA$ for 2.

The geometry around Tl is a distorted square-based pyramid in which the apical site is occupied by a chelating bidentate $\mathrm{OAc}^{-}$group, whereas that around the $\mathrm{Ga}^{3+}$ is described as a distorted trigonal bipyramid with $\mathrm{O}(3), \mathrm{N}(3)$, and $\mathrm{N}(5)$ lying in the equatorial plane. The distance between $\mathrm{Ga}(1)$ and $\mathrm{O}(4)$ is $2.865 \AA$. The pyrrole nitrogens $\mathrm{N}(4)$ and $\mathrm{N}(1)$ are no longer bonded to the thallium and gallium as indicated by their longer internuclear distances, $2.944 \AA$ for $\mathrm{Tl} \cdots \mathrm{N}(4)$ and $2.641 \AA$ for $\mathrm{Ga}(1) \cdots \mathrm{N}(1)$. The $\mathrm{Tl}-\mathrm{N}(2)$ bond trans to the $\mathrm{N}(5)$ position in compound $\mathbf{1}$ is somewhat shorter than the other two $\mathrm{Tl}-\mathrm{N}$ bond distances (i.e., 2.152(7) $\AA$ for $\mathrm{Tl}-\mathrm{N}(2)$ compared to 2.347(7) $\AA$ for $\mathrm{Tl}-\mathrm{N}(1)$ and $2.361(7) \AA$ for $\mathrm{Tl}-\mathrm{N}(3))$. Likewise, the $\mathrm{Ga}(1)-\mathrm{N}(3)$ bond in compound 2 is slightly shorter than the

other two $\mathrm{Ga}-\mathrm{N}$ distances [1.911(3) $\AA$ for $\mathrm{Ga}(1)-\mathrm{N}(3)$ vs $2.031(3) \AA$ for the two equivalent $\mathrm{Ga}(1)-\mathrm{N}(2)$ and $\mathrm{Ga}(1)-\mathrm{N}(4)$ distances]. Figure 2 indicates the actual porphyrin skeleton for $\mathbf{1}$ and $\mathbf{2}$; the four pyrrole nitrogens $\mathrm{N}(1)-\mathrm{N}(4)$ are approximately coplanar (i.e., 4 N plane) within $\pm 0.01 \AA$ for $\mathbf{1}$ (Figure 2a) but

(a) $\mathrm{Tl}(\mathrm{N}-\mathrm{NTs}-\mathrm{tpp})(\mathrm{OAc})$

## (b) $\mathrm{Ga}(\mathrm{N}-\mathrm{NTs}-\mathrm{tpp})(\mathrm{OAc})$

Figure 1. Molecular configuration and atom-labeling scheme for (a) $\mathrm{Tl}(\mathrm{N}-\mathrm{NTs}-\operatorname{tpp})(\mathrm{OAc}) \cdot 0.75 \mathrm{CHCl}_{3}$ (or $\mathbf{1} \cdot 0.75 \mathrm{CHCl}_{3}$ ) and (b) $\mathrm{Ga}(\mathrm{N}-$ NTs-tpp)(OAc) (2), with ellipsoids drawn at $30 \%$ probability. Hydrogen atoms for both compounds and solvents $\mathrm{C}(70) \mathrm{H}(70 \mathrm{a}) \mathrm{Cl}(1)$ $\mathrm{Cl}(2) \mathrm{Cl}(3)$ for $\mathbf{1} \cdot 0.75 \mathrm{CHCl}_{3}$ are omitted for clarity.
$\pm 0.15 \AA$ for 2 (Figure 2b). The tosyl amide nitrogen $\mathrm{N}(5)$ in $\mathbf{1}$ and 2 are located considerably far from the ( 4 N ) plane. In complex 1, $\mathrm{Tl}^{3+}$ and $\mathrm{N}(5)$ are located on the same side at 1.17 and $1.27 \AA$ from its ( 4 N ) plane, but for complex 2, $\mathrm{Ga}^{3+}$ and $\mathrm{N}(5)$ are located on different sides at -0.28 and $0.96 \AA$ from its 4 N plane (Figure 2). Apparently, chelating bidentate acetate in $\mathbf{1}$ is cis to the $N$-tosyl group with $\mathrm{O}(1)$ and $\mathrm{O}(2)$ being located separately at 3.11 and $3.04 \AA$ out of the 4 N plane, and monodentate acetate in $\mathbf{2}$ is trans to the $N$-tosyl group with $\mathrm{O}(3)$ located at $-1.98 \AA$ out of the 4 N plane. The porphyrin marocycle is indeed distorted because of the presence of the $N$-tosyl group. Thus, the $\mathrm{N}(4)$ and $\mathrm{N}(1)$ pyrrole rings bearing the $N$-tosyl group would deviate mostly from the ( 4 N ) plane and would be oriented separately in a dihedral angle of $51.3^{\circ}$ and of $33.5^{\circ}$, whereas small angles of $6.0^{\circ}, 7.4^{\circ}$, and $9.6^{\circ}$ occur with $\mathrm{N}(2), \mathrm{N}(1)$, and $\mathrm{N}(3)$ pyrroles for compound $\mathbf{1}$ and $4.8^{\circ}$, $8.1^{\circ}$, and $10.4^{\circ}$ with $\mathrm{N}(4), \mathrm{N}(2)$, and $\mathrm{N}(3)$ pyrroles for compound 2 (see also Table 5 in Supporting Information). In compound

(a) $\mathrm{Tl}(\mathrm{N}-\mathrm{NTs}-\mathrm{tpp})(\mathrm{OAc})$

(b) $\mathrm{Ga}(\mathrm{N}-\mathrm{NTs}-\mathrm{tpp})(\mathrm{OAc})$

Figure 2. Diagram of the porphyrinato core $\left(\mathrm{C}_{20} \mathrm{~N}_{4}, \mathrm{M}, \mathrm{NTs}\right.$, and $\mathrm{OAc}^{-}$) of (a) compound 1 and (b) compound 2. The values represent the displacements (in $\AA$ ) of the atoms from the mean 3 N plane (i.e., $\mathrm{N}(1)-\mathrm{N}(3)$ for $\mathbf{1}$ and $\mathrm{N}(2)-\mathrm{N}(4)$ for $\mathbf{2})$ and the parenthesized values from the mean 4 N plane (i.e., $\mathrm{N}(1)-\mathrm{N}(4)$ ).

1, such a large deviation from planarity for the $\mathrm{N}(4)$ pyrrole (Table 2) is also reflected by observing a $16-21 \mathrm{ppm}$ upfield shift of the $\mathrm{C}_{\beta}(\mathrm{C} 17, \mathrm{C} 18)$ at 115.6 ppm compared to 136.4 ppm for $\mathrm{C}_{\beta}(\mathrm{C} 3, \mathrm{C} 12), 133.8 \mathrm{ppm}$ for $\mathrm{C}_{\beta}(\mathrm{C} 2, \mathrm{C} 13)$, and 132.3 ppm for $\mathrm{C}_{\beta}(\mathrm{C} 7, \mathrm{C} 8)$. In compound 2 , a similar deviation is also found for the $\mathrm{N}(1)$ pyrrole (Table 2) by observing a $10-15$ ppm upfield shift of the $\mathrm{C}_{\beta}(\mathrm{C} 19, \mathrm{C} 20)$ at 119.7 ppm compared to 135.0 for $\mathrm{C}_{\beta}(\mathrm{C} 5, \mathrm{C} 14), 133.2 \mathrm{ppm}$ for $\mathrm{C}_{\beta}(\mathrm{C} 9, \mathrm{C} 10)$, and 129.8 ppm for $\mathrm{C}_{\beta}(\mathrm{C} 4, \mathrm{C} 15)$. The distortion in $\mathbf{1}$ is larger than that present in the $\mathrm{Ni}(\mathrm{N}-\mathrm{NTs}-\mathrm{tpp})$ complex in which the dihedral angle between the mean plane of one pyrrole ring and the mean plane of the four pyrrole nitrogens $(4 \mathrm{~N})$ is as large as $40.5^{\circ}$. Because of the larger size of the $\mathrm{Tl}^{3+}$, the acetate ligand is bidentately chelated to the Tl atom, while it is unidentately coordinated to the Ga atom. Likewise, because of the same large size of the $\mathrm{Tl}^{3+}, \mathrm{Tl}$ and $\mathrm{N}(5)$ lie 1.17 and $1.27 \AA$ above the 4 N
plane in $\mathbf{1}$ compared to $0.21 \AA$ for Ni and $0.94 \AA$ for the nitrogen atom of the nitrene fragment in $\mathrm{Ni}(\mathrm{N}-\mathrm{NTs}-\mathrm{tpp}) .^{3}$

The pyrrole ring nitrogens $\mathrm{N}(4)$ and $\mathrm{N}(1)$ are actually inclined toward the Tl and Ga atoms in $\mathbf{1}$ and $\mathbf{2}$, respectively. These distortions re-form the distances between opposite pyrrole nitrogen atoms to be unusual. The normal diameter of the "hole" in an undistorted metalloporphyrin complex has been estimated to be $4.02 \AA .{ }^{15}$ In $\mathbf{1}$, the $\mathrm{N}(2) \cdots \mathrm{N}(4)($ or $\mathrm{N}(1) \cdots \mathrm{N}(3))$ distance is $4.515 \AA$ (or 4.029), and in 2 the $\mathrm{N}(1) \cdots \mathrm{N}(3)$ (or $\mathrm{N}(2) \cdots \mathrm{N}(4)$ ) distance is $4.464 \AA$ (or 4.042); it is caused by the large deviation of the $N(4)$ pyrrole and $N(1)$ pyrrole from the $4 N$ plane for $\mathbf{1}$ and 2, respectively. Hence, in $\mathbf{1}$ and 2, the thallium(III) and gallium(III) atoms are all bound in an expanded porphyrinato $(4 \mathrm{~N})$ core. The plane $(P)$ defined by $\mathrm{Tl}, \mathrm{N}(5), \mathrm{N}(4)$, and the sulfur atom S , and the other plane by $\mathrm{Ga}(1), \mathrm{N}(5), \mathrm{N}(1)$, and $S(1)$ are almost perpendicular to the $(4 \mathrm{~N})$ plane, $84.4^{\circ}$ for $\mathbf{1}$ and $90.3^{\circ}$ for $\mathbf{2}$. The tosyl group (T) (i.e., the plane $T$ ) is bonded to $\mathrm{N}(5)$ so that it lies above the macrocycle, orienting in a dihedral angle of $12.8^{\circ}$ and $11.5^{\circ}$ with the 4 N plane in $\mathbf{1}$ and $\mathbf{2}$, respectively (Table 5 in Supporting Information). The dihedral angles between the mean plane of the skeleton $(4 \mathrm{~N})$ and the planes of the phenyl group are $55.7^{\circ}(\mathrm{C}(31)), 87.3^{\circ}(\mathrm{C}(41))$, $34.7^{\circ}(\mathrm{C}(51))$, and $50.1^{\circ}(\mathrm{C}(61))$ for $\mathbf{1}$ and $73.0^{\circ}(\mathrm{C}(33))$, $84.3^{\circ}$ $(\mathrm{C}(27)), 75.4^{\circ}(\mathrm{C}(21))$, and $57.4^{\circ}(\mathrm{C}(39))$ for 2 (Table 5 in Supporting Information).

In comparison with a distorted trigonal bipyrimidal structure of $\mathrm{Fe}(\mathrm{N}-\mathrm{NTs}-\mathrm{tpp}) \mathrm{Cl},{ }^{7}$ the individual planar pyrrole rings, bearing respectively the $\mathrm{N}(1), \mathrm{N}(2), \mathrm{N}(3)$, and $\mathrm{N}(4)$ nitrogen atoms in 2 , orient in dihedral angles of $24.5^{\circ}, 1.7^{\circ}, 2.2^{\circ}$, and $6.1^{\circ}$ with respect to the 3 N plane, which contains the three pyrrole nitrogens $\mathrm{N}(2), \mathrm{N}(3)$, and $\mathrm{N}(4)$ bonded to the gallium (Table 5 in Supporting Information). This distortion is, however, smaller than that present in the $\mathrm{Fe}(\mathrm{N}-\mathrm{NTs}-\mathrm{tpp}) \mathrm{Cl}$ complex in which the corresponding dihedral angles are $29.9^{\circ}, 8.5^{\circ}, 5.8^{\circ}$, and $9.8^{\circ}$, respectively. ${ }^{7}$ The pyrrole nitrogen $\mathrm{N}(1)$, not bonded to the gallium, lies $0.67 \AA$ above the average plane of 3 N (Figure 2b). Moreover, the gallium atom lies $-0.15 \AA$ below this plane toward the $\mathrm{O}(3)$ atom. In $\mathrm{Fe}(\mathrm{N}-\mathrm{NTs}-$ tpp $) \mathrm{Cl},{ }^{7}$ the corresponding pyrrole nitrogen N 23 lies $0.44 \AA$ above the 3 N plane but the iron atom lies $-0.21 \AA$ below this plane toward the chlorine atom. Hence, the X-ray structure of compound $\mathbf{2}$ is quite similar to that of $\mathrm{Fe}(\mathrm{N}-\mathrm{NTs}-\mathrm{tpp}) \mathrm{Cl}$ except that the latter is a paramagnetic complex.

The distortion of the porphyrin skeleton seems to have very little or no effect at all on the $\pi$-electron delocalization in the porphyrinato core. By use of $\mathrm{C}_{\alpha}$ and $\mathrm{C}_{\beta}$ to denote the respective $\alpha$ - and $\beta$-carbon atoms of a pyrrole ring, $\mathrm{C}_{\mathrm{m}}$ for methine carbon, and $C_{p}$ for a phenyl carbon atom that is bonded to the core, the averaged bond lengths in the porphine skeleton are $\mathrm{N}-\mathrm{C}_{\alpha}=$ 1.39 (1) (or 1.376(4)), $\mathrm{C}_{\alpha}-\mathrm{C}_{\beta}=1.43(1)$ (or 1.427(5)), $\mathrm{C}_{\beta}-\mathrm{C}_{\beta}=1.35(1)$ (or 1.347(5)), $\mathrm{C}_{\alpha}-\mathrm{C}_{m}=1.41$ (1) (or 1.403(5)), and $\mathrm{C}_{\mathrm{m}}-\mathrm{C}_{\mathrm{p}}=1.50$ (1) $\AA$ (or 1.497(5)) for compound $\mathbf{1}$ (or 2). These distances are almost identical with those found in nondistorted porphyrin complexes for $\mathrm{Tl}(\mathrm{tpp})(\mathrm{OAc})^{13}$ (or $\mathrm{Ga}(\mathrm{tpp})(\mathrm{OAc})) .{ }^{14}$ This has also been observed in the previously described porphyrin derivatives in which a nitrene moiety is inserted into a metal-pyrrole nitrogen bond. ${ }^{3,7,8}$

The major difference between six-coordinate (1) and fivecoordinate (2) complexes is the movement of the metal toward the 3 N (or 4 N ) plane in the five-coordinate complex compared to the six-coordinate complex. In the binding to the $\mathrm{OAc}^{-}$ligand in 2 with $\mathrm{CN}=5$, the smaller $\mathrm{Ga}(\mathrm{III})$ ion is forced to lie below
(15) Collins, D. M.; Hoard, J. L. J. Am. Chem. Soc. 1970, 92, 3761.
the 3 N ( or 4 N ) plane of the macrocycle. Hence, in $\mathbf{2}$ the distance between Ga and the 3 N (or 4 N ) plane is only -0.15 (or -0.28 ) $\AA$, while in 1 with $\mathrm{CN}=6$ this distance is much larger, $\sim 1.18$ (or $\sim 1.17$ ) $\AA$ for the larger $\mathrm{Tl}(\mathrm{III})$ ion.
${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ for $\mathrm{Tl}(\mathrm{N}-\mathrm{NTs}-\operatorname{tpp})(\mathrm{OAc})$ (1) and $\mathrm{Ga}\left(\mathrm{N}^{-}\right.$ NTs-tpp)(OAc) (2) in $\mathrm{CDCl}_{3}$ and $\mathrm{CD}_{\mathbf{2}} \mathrm{Cl}_{\mathbf{2}}$. Complexes 1 and 2 were characterized by ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra. In solution, where the phenyl, $N$-tosyl, and acetate groups are free to rotate, the molecule has effective $C_{s}$ symmetry with a mirror plane running through the $\mathrm{N}(2)-\mathrm{Tl}-\mathrm{N}(5)-\mathrm{N}(4)$ unit for $\mathbf{1}$ or the $\mathrm{N}(3)-\mathrm{Ga}(1)-\mathrm{N}(5)-\mathrm{N}(1)$ unit for 2. There are four distinct $\beta$-pyrrole protons $\mathrm{H}_{\beta}$, four $\beta$-pyrrole carbons $\mathrm{C}_{\beta}$, four $\alpha$-pyrrole carbons $\mathrm{C}_{\alpha}$, two different meso carbons $\mathrm{C}_{\text {meso }}$, and two phenyl$\mathrm{C}_{1}$ carbons for both complexes (Tables 1 and 2). In compound 1, the average distance between $\mathrm{Tl} \cdots \mathrm{C}(7)$ and $\mathrm{Tl} \cdots \mathrm{C}(8), \mathrm{Tl} \cdots$ $\mathrm{C}(3)$ and $\mathrm{Tl} \cdots \mathrm{C}(12), \mathrm{Tl} \cdots \mathrm{C}(2)$ and $\mathrm{Tl} \cdots \mathrm{C}(13)$, and $\mathrm{Tl} \cdots \mathrm{C}(17)$ and $\mathrm{Tl} \cdots \mathrm{C}(18)$ increases from $4.258,4.294,4.415$ to $4.712 \AA$. The NMR data of $\mathbf{1}$ showed four different types of $\mathrm{Tl}-\mathrm{H}$ coupling constants for $\mathrm{H}_{\beta}$ (Figure 3 and Table 1). The doublet at 8.75 ppm is assigned as $\mathrm{H}_{\beta(7,8)}$ with ${ }^{4} J(\mathrm{Tl}-\mathrm{H})=75.6 \mathrm{~Hz}$. The doublet of a doublet at 9.13 ppm is due to $\mathrm{H}_{\beta(3,12)}$ with ${ }^{4} J(\mathrm{Tl}-\mathrm{H})=18 \mathrm{~Hz}$ and ${ }^{3} J(\mathrm{H}-\mathrm{H})=4.5 \mathrm{~Hz}$. The doublet of a doublet again at 8.98 ppm is due to $\mathrm{H}_{\beta(2,13)}$ with ${ }^{4} J(\mathrm{Tl}-\mathrm{H})=$ 10 Hz and ${ }^{3} J(\mathrm{H}-\mathrm{H})=4.5 \mathrm{~Hz}$, and the singlet at 6.99 ppm is due to $\mathrm{H}_{\beta(17,18)}$ with ${ }^{5} J(\mathrm{Tl}-\mathrm{H})$ being unobserved. Likewise, there were also four different types of $\mathrm{Tl}-{ }^{13} \mathrm{C}$ coupling constants for $\mathrm{C}_{\beta}$ (Table 2). The doublet at 132.3 ppm is due to $\mathrm{C}_{\beta}(\mathrm{C} 7, \mathrm{C} 8)$ with ${ }^{3} J\left(\mathrm{Tl}-{ }^{13} \mathrm{C}\right)=161 \mathrm{~Hz}$. The doublet at 136.4 ppm is due to $\mathrm{C}_{\beta}(\mathrm{C} 3, \mathrm{C} 12)$ with ${ }^{3} J\left(\mathrm{Tl}-{ }^{13} \mathrm{C}\right)=38 \mathrm{~Hz}$. The singlet at 133.8 ppm is due to $\mathrm{C}_{\beta}(\mathrm{C} 2, \mathrm{C} 13)$ with ${ }^{3} \mathrm{~J}\left(\mathrm{Tl}-{ }^{13} \mathrm{C}\right)$ being unobserved, and the doublet at 115.6 ppm is due to $\mathrm{C}_{\beta}(\mathrm{C} 17, \mathrm{C} 18)$ with ${ }^{4} J\left(\mathrm{Tl}-{ }^{13} \mathrm{C}\right)=79 \mathrm{~Hz}$. The ${ }^{1} \mathrm{H}$ NMR spectra (Figure 3) reveal that the aromatic protons of the tosyl groups appear as doublets at 6.96 (tosyl $-\mathrm{H}_{3,5}$ ) and $6.26 \mathrm{ppm}\left(\right.$ tosyl $\left.-\mathrm{H}_{2,6}\right)$ for $\mathbf{1}$ and at 6.47 and 4.80 ppm for $\mathbf{2}$. All tosylimido and acetato protons are shifted upfield compared to their counterparts on free NHTs and $\mathrm{OAc}^{-}$. Such a shift is presumably attributed to the porphyrin ring current effect. On the basis of the ring model, ${ }^{16}$ as the distance between the geometrical center $\left(\mathrm{C}_{\mathrm{t}}\right)$ of the 4 N plane and axial protons gets smaller, the shielding effect becomes larger. The $\left(\mathrm{C}_{\mathrm{t}} \cdots\right.$ axial proton $)$ distance can be estimated from $\mathrm{C}_{\mathrm{t}}$ to the carbons bearing the axial protons. The average distances (in $\AA$ ) for $\mathrm{C}_{\mathrm{t}} \cdots$ tosyl- $\mathrm{C}_{2,6}, \mathrm{C}_{\mathrm{t}} \cdots$ tosyl- $\mathrm{C}_{3,5}, \mathrm{C}_{\mathrm{t}} \cdots$ tosyl$\mathrm{CH}_{3}$, and $\mathrm{C}_{\mathrm{t}} \cdots \mathrm{CH}_{3}(\mathrm{OAc})$ are $5.282,6.364,8.159$, and 5.374 in 1, and 4.397, 5.424, 7.190, and 4.339 in 2. The fact that all four bond distances in $\mathbf{2}$ are shorter than those in $\mathbf{1}$ indicates that the ring current effect in $\mathbf{2}$ would be larger and in turn the ${ }^{1} \mathrm{H}$ upfield shifts for the axial protons in 2 would be still higher. This is what exactly observed: -1.21 ppm in $\mathbf{1}$ and 0.78 ppm in 2 for OAc, 2.11 and 2.31 for tosyl- $\mathrm{CH}_{3}, 4.80$ and 6.26 for tosyl $-\mathrm{H}_{2,6}$, and 6.47 and 6.96 for tosyl $-\mathrm{H}_{3,5}$. The above ring current effect indicates that both the tosyl and acetate ligands are bonded to Tl in $\mathbf{1}$ and to Ga in $\mathbf{2}$. This bonding argument is further confirmed by the result that the tosyl- $\mathrm{C}_{1}$ (i.e., $\mathrm{C}(23)$ ) in 1 was observed at 137.5 ppm with ${ }^{3} \mathrm{~J}(\mathrm{Tl}-\mathrm{C})=47 \mathrm{~Hz}$.

Dynamical NMR of $\mathbf{1}$ in $\mathbf{C D}_{\mathbf{2}} \mathbf{C l}_{\mathbf{2}}$. When a $0.02 \mathbf{M}$ solution of $\mathrm{Tl}(\mathrm{N}-\mathrm{NTs}-\mathrm{tpp})(\mathrm{OAc})(\mathbf{1})$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ (Figure 4) was recorded at low temperature, the methyl protons of $\mathrm{OAc}^{-}$appeared as a single peak at $24^{\circ} \mathrm{C}(\delta=0.67 \mathrm{ppm})$. At $-110^{\circ} \mathrm{C}$ the singlet first broadened (coalescence temperature $T_{\mathrm{c}}=-102{ }^{\circ} \mathrm{C}$ ) and then split into two peaks with a separation of 16.2 Hz . Since the exchange of $\mathrm{OAc}^{-}$within $\mathbf{1}$ is reversible, the results observed at 599.95 MHz confirm that the separation results from a

Figure 3. ${ }^{1} \mathrm{H}$ NMR spectra for (a) $\mathrm{Tl}(\mathrm{N}-\mathrm{NTs}-\operatorname{tpp})(\mathrm{OAc})$ (1) at 299.94 MHz and (b) $\mathrm{Ga}(\mathrm{N}-\mathrm{NTs}-\mathrm{tpp})(\mathrm{OAc})(\mathbf{2})$ at 599.95 MHz in $\mathrm{CDCl}_{3}$ at $24^{\circ} \mathrm{C} . \phi$ represents the phenyl protons.
coupling of ${ }^{4} J(\mathrm{Tl}-\mathrm{H})$ rather than a chemical shift difference. The most likely cause of loss of coupling is reversible dissociation of acetate

$$
\begin{equation*}
\mathrm{Tl}(\mathrm{~N}-\mathrm{NTs}-\mathrm{tpp})(\mathrm{OAc}) \rightleftharpoons \mathrm{Tl}(\mathrm{~N}-\mathrm{NTs}-\mathrm{tpp})^{+}+\mathrm{OAc}^{-} \tag{1}
\end{equation*}
$$

with a small dissociation constant but reasonable rate at room temperature. ${ }^{17}$ Such a scenario would lead to little change in the chemical shift with temperature and no detectable free $\mathrm{OAc}^{-}$ and $\mathrm{Tl}(\mathrm{N}-\mathrm{NTs}-\mathrm{tpp})^{+}$at low temperature but would result in the loss of coupling between acetate and thallium at higher temperatures. The chemical shift observed at high temperature

16 Hz

Figure 4. The $599.95 \mathrm{MHz}{ }^{1} \mathrm{H}$ NMR spectra for the axial acetato protons of $\mathrm{Tl}(\mathrm{N}-\mathrm{NTs}-\operatorname{tpp})(\mathrm{OAc})(\mathbf{1})$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ at various temperatures.
is the average of two species (i.e., $\mathrm{Tl}(\mathrm{N}-\mathrm{NTs}-\mathrm{tpp})(\mathrm{OAc})$ and $\mathrm{OAc}^{-}$) in eq 1 weighted by their concentration. A comparison of observed and computed spectra yields $\Delta G^{\ddagger}{ }_{171}=36.0 \mathrm{~kJ} /$ mol . At $24^{\circ} \mathrm{C}$, intermolecular exchange of the $\mathrm{OAc}^{-}$group is rapid, indicated by singlet signals due to carbonyl carbons at 176.4 ppm and methyl carbons at 19.1 ppm . At $-110^{\circ} \mathrm{C}$, the rate of intermolecular exchange of $\mathrm{OAc}^{-}$for $\mathbf{1}$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ is slow. Hence, at this temperature, the methyl and carbonyl carbons of $\mathrm{OAc}^{-}$are observed at 18.5 ppm [with ${ }^{3} J(\mathrm{Tl}-\mathrm{C})=$ 220 Hz ] and 176.3 ppm [with ${ }^{2} J(\mathrm{Tl}-\mathrm{C})=205 \mathrm{~Hz}$ ], respectively. These ${ }^{13} \mathrm{C}$ resonances are quite close to the $\mathrm{Tl}(\mathrm{tpp})(\mathrm{OAc})$ case in which the two corresponding carbons were observed, in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ at $-90^{\circ} \mathrm{C}$, at 18.8 ppm [with ${ }^{3} \mathrm{~J}(\mathrm{Tl}-\mathrm{C})=280 \mathrm{~Hz}$ ], and $174.9 \mathrm{ppm}\left[\right.$ with ${ }^{2} J(\mathrm{Tl}-\mathrm{C})=235 \mathrm{~Hz}$ ]. ${ }^{12,13}$ For 2 in $\mathrm{CDCl}_{3}$ at 24 and $-50^{\circ} \mathrm{C}$, the corresponding carbons were observed at 19.2 and 168.7, close to those of $20.4 \mathrm{ppm}\left(\mathrm{CH}_{3}\right)$ and 168.8 $\mathrm{ppm}(\mathrm{CO})$ in $\mathrm{Ga}(\mathrm{tpp})(\mathrm{OAc}) .{ }^{14}$ On the basis of our previous report, ${ }^{11}$ the carbonyl chemical shifts at 176.4 ppm (within the
value of $175.2 \pm 1.6 \mathrm{ppm}$ ) for $\mathbf{1}$ and at 168.7 (within the range of $168.2 \pm 1.7 \mathrm{ppm}$ ) for 2 at $24^{\circ} \mathrm{C}$ also confirm that the $\mathrm{OAc}^{-}$ group is bidentately chelated to the Tl atom but unidentately coordinated to the Ga atom.

UV/Visible Absorption Spectra of 1 and 2. The electronic spectrum of 1 in $\mathrm{CHCl}_{3}$ has three $\lambda_{\text {max }}$ at $446(\mathrm{~B}(0,0)), 558$ $(\mathrm{Q}(1,0))$, and $602(\mathrm{Q}(0,0))$ that are comparable to those of 433 , 567 , and 607 nm found for $\mathrm{Tl}(\mathrm{tpp})(\mathrm{OAc}),{ }^{18,19}$ a cisoid sixcoordinate thallium(III) porphyrin complex. On the other hand, the electronic spectrum of 2 has three $\lambda_{\text {max }}$ at $436(B(0,0)), 544$ $(\mathrm{Q}(1,0))$, and $587(\mathrm{~B}(0,0))$, which are also quite closer to those of 420,552 , and 586 for $\mathrm{Ga}(\mathrm{tpp})(\mathrm{OAc}),{ }^{20}$ a typical fivecoordinate gallium(III) porphyrin complex.

## Conclusions

We have investigated two novel diamagnetic, mononuclear, and bridged metal complexes of N -tosylamidoporphyrin having an $\mathrm{M}^{\mathrm{III}}-\mathrm{NTs}-\mathrm{N}$ linkage, and their X-ray structures are studied. The ${ }^{13} \mathrm{C}$ chemical shifts of the carbonyl carbon are used to identify the coordinate mode of the acetato group. Dynamical ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra of the acetato group in $\mathbf{1}$ reveal that this group undergoes an intermolecular exchange with a free energy of activation, $\Delta G^{\ddagger}{ }_{171}=36.0 \mathrm{~kJ} / \mathrm{mol}$.
