#### Abstract

Manganese(I) complexes fac- $\left(\eta^{2}-\mathrm{P}_{3-n} \mathrm{~S}_{n}\right) \mathrm{Mn}(\mathrm{CO})_{3} \mathrm{Br}(n=0-3)\left[\mathrm{P}_{3} \mathrm{~W}=\mathrm{Z}=\mathrm{PPh}_{2} ; \mathrm{P}_{2} \mathrm{~S} \mathrm{~W}=\right.$ $\mathrm{PPh}_{2}, \mathrm{Z}=\mathrm{SPh} ; \mathrm{PS}_{2} \mathrm{Z}=\mathrm{SPh}, \mathrm{W}=\mathrm{PPh}_{2} ; \mathrm{S}_{3} \mathrm{~W}=\mathrm{Z}=\mathrm{SPh}$ in $\left.\mathrm{CH}_{3} \mathrm{C}\left(\mathrm{CH}_{2} \mathrm{~W}\right)_{2}\left(\mathrm{CH}_{2} \mathrm{Z}\right)\right]$ formed from the corresponding tripodal ligand have been prepared and isolated as pairs of isomers. The reaction of $\mathrm{P}_{2} \mathrm{~S}$ with $\mathrm{BrMn}(\mathrm{CO})_{5}$ in chloroform produced a pair of stereoisomers, syn$f a c-\left(P, P^{\prime}-\mathrm{P}_{2} \mathrm{~S}\right) \mathrm{Mn}(\mathrm{CO})_{3} \mathrm{Br}(1 \mathrm{a})$ and anti-fac- $\left(P, P^{\prime}-\mathrm{P}_{2} \mathrm{~S}\right) \mathrm{Mn}(\mathrm{CO})_{3} \mathrm{Br}(1 \mathrm{~b})$, which were separated and fully characterized. Equilibration ( $K_{1}=2 / 3$ ) between 1a and $\mathbf{1 b}$ was established. For PS $_{2}$, the equilibrium constant $\left(K_{2}\right)$ between syn-fac- $\left(P, S-\mathrm{PS}_{2}\right) \mathrm{Mn}(\mathrm{CO})_{3} \mathrm{Br}(2 \mathrm{a})$ and anti-fac- $(P, S$ $\left.\mathrm{PS}_{2}\right) \mathrm{Mn}(\mathrm{CO})_{3} \mathrm{Br}(2 \mathrm{~b})$ was unity. Kinetic studies of isomerization of $1 \mathbf{a}$ to $1 \mathbf{b}$ and 2 a to 2 b were carried out by using an NMR spectrometer. The activation parameters were obtained: $\Delta H^{t_{1 a}}$ $=30.5 \pm 0.4 \mathrm{kcal} / \mathrm{mol}, \Delta S^{\ddagger}{ }_{1 \mathrm{a}}=11 \pm 1$ eu for complex $1 \mathrm{a} ; \Delta H^{\ddagger}{ }_{2 \mathrm{a}}=24.9 \pm 0.7 \mathrm{kcal} / \mathrm{mol}, \Delta S^{*}{ }_{2 \mathrm{a}}$ $=7 \pm 2$ eu for complex 2a. A mechanistic pathway for these isomerizations is proposed. Crystal structures were determined for three complexes: 1a, 1b, and 2a. X-ray data were collected on a CAD-4 diffractometer at room temperature and were refined by a least-squares treatment. For 1a: $a=10.669(2) ~ \AA, b=17.864(3) \AA, c=18.841(12) ~ \AA, \beta=105.30(2)^{\circ}$, monoclinic, $Z=4$, $P 2_{1 / \mathrm{c}}, R\left(F_{0}\right)=0.051, R_{\varpi}\left(F_{0}\right)=0.042$ for 3043 reflections with $I_{0}>2 \sigma\left(I_{0}\right)$. For 2b: $a=10.855(3)$ $\AA, b=20.322(7) \AA, c=17.887(9) \AA, \beta=104.73(3)^{\circ}$, monoclinic, $Z=4, P 2_{1 / n}, R\left(F_{0}\right)=0.059, R_{w}\left(F_{0}\right)$ $=0.047$ for 3316 reflections with $I_{0}>2 \sigma\left(I_{0}\right)$. For 2a: $a=8.670(5) ~ \AA, b=9.539(3) \AA, c=18.921$ (9) $\AA, a=93.09(3)^{\circ}, \beta=90.27(5)^{\circ}, \gamma=101.21(4)^{\circ}$, triclinic, $Z=2, P \overline{1}, R\left(F_{0}\right)=0.052, R_{w}\left(F_{0}\right)=0.054$ for 2513 reflections with $I_{0}>2 \sigma\left(I_{0}\right)$. The conformations of the chelate rings are discussed.

## Introduction

The development of various polydentate phosphine ligands for coordination chemistry and homogeneous catalysis has received much attention in recent years. Of particular interest are "hybrid" donor polydentate ligands, which allow some weak donors to form transition metal (TM) complexes through the chelate effect. The relatively poor $\sigma$-donor and $\pi$-acceptor natures of a simple thioether, compared to phosphine, make a metal-sulfur (TM-S) bond quite weak, especially with those transition metals in low oxidation states. ${ }^{1-3}$. By means of chelates involving "hybrid" sulfur and phosphorus ligands, the preparation of TM-S complexes has become increasingly feasible and reports of many of P-S hybrid ligands have appeared. ${ }^{4}$ We described the synthesis of 2,2-bis((diphenylphosphi-

[^0]no)methyl)-1-(phenylthio)propane $\left(\mathrm{P}_{2} \mathrm{~S}\right)^{5}$ and 2,2-bis-((phenylthio)methyl)-1-(diphenylphosphino)propane $\left(\mathrm{PS}_{2}\right) .{ }^{6}$ The weak interaction of thioether sites in both ligands with various transition metals was illustrated. Thus, the thioether site in $\mathrm{P}_{2} \mathrm{~S}$ remains uncoordinated in the complexes of $(\mathrm{CO})_{4} \mathrm{M}\left(\eta^{2}-\mathrm{P}_{2} \mathrm{~S}\right)(\mathrm{M}=\mathrm{Cr}, \mathrm{Mo}),{ }^{5}$ unlike $(\mathrm{CO})_{3} \mathrm{M}\left(\eta^{3}-\mathrm{P}_{3}\right)(\mathrm{M}=\mathrm{Cr}, \mathrm{Mo}),{ }^{7}$ where $\mathrm{P}_{3}=\mathrm{CH}_{3} \mathrm{C}\left(\mathrm{PPh}_{2}\right)_{3}$. We also observed the intramolecular exchange of sulfur sites in the complex $\left(\mathrm{PS}_{2}\right) \mathrm{PdCl}_{2}$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ solution. ${ }^{6}$

The complexes of thioether with manganese(I) have been little investigated. ${ }^{1-3,7,8}$ Due to the imposed facial geometry of the tripod, tripodal ligands $\mathrm{P}_{3-n} \mathrm{~S}_{n}(n=0-3)$ may be suitable for systematic investigation of the interaction of $\mathrm{Mn}(\mathrm{I})-\mathrm{S}$. We describe here our works on the coordination chemistry of $\mathrm{Mn}(\mathrm{I})$ with tripodal ligands.

## Results and Discussion

Coordination of $P_{n} \mathbf{S}_{3-n}$ toward $\mathbf{M n}(I)$. An equimolar mixture of bromopentacarbonylmanganese(I) and $\mathrm{P}_{n} \mathrm{~S}_{8-n}$ ( $n=1-3$ ) in chloroform (eq 1) was heated at reflux until the infrared spectra of the carbonyl region changed no further. The desired complexes were then isolated by crystallization in almost quantitative yield. For $\mathrm{P}_{2} \mathrm{~S}$, the thermal reaction provided a mixture of $1 a$ and $1 b$ in a ratio of $3: 2$. Both complexes have similar carbonyl

[^1]
absorptions in their infrared spectra, and those peaks are characteristic of $f a c-\mathrm{L}_{2} \mathrm{Mn}(\mathrm{CO})_{3} \mathrm{Br} .{ }^{9}$ The separation of 1a and 1 lb was achieved by fractional recrystallization in dichloromethane and hexane; complex la crystallized first as a yellow crystalline solid whereas 1 b precipitated as an orange crystalline solid. With the use of single-crystal analyses of $\mathbf{1 a}$ and $\mathbf{1 b}$, we determined their isomeric structures; their ORTEP plots appear in Figures 1 and 2, respectively. In both 1a and 1b, the sulfur donor remained uncoordinated; the difference between these two isomers is the uncoordinated (phenylthio)methyl substituent situated either opposite ( $\mathbf{l b}$, anti isomer) to or on the same side (1a, syn isomer) as the bromide ligand along the sixmembered chelate ring. Both complexes have almost identical spectral data (see Experimental Section), except for ${ }^{1} \mathrm{H}$ NMR signals. The chemical shift of the methyl group in la ( $\delta 1.13$ ) is quite downfield from that in $\mathbf{1 b}$ ( $\delta$ 0.36 ). That the product ratio between $1 \mathbf{a}$ and $1 \mathbf{1 b}(3: 2)$ was a result of thermodynamic distribution is demonstrated by the following evidence. When a pure complex of either la or 1 b was heated in boiling chloroform for 14 h , a mixture of 1 a and 1 b was obtained in a ratio of 6:4 ( $K_{1}=2 / 3$ ). Hence complex 1a is more stable than 1 b by only 0.24 $\mathrm{kcal} / \mathrm{mol}$ at 298 K .
Similarly to $\mathrm{P}_{2} \mathrm{~S}$, the thermal substitution reaction of $\mathrm{Mn}(\mathrm{CO})_{5} \mathrm{Br}$ with $\mathrm{PS}_{2}$ gave two stereoisomeric products $2 a$ and $2 b$ in a ratio of $1: 1$. Complex $2 a$ was obtained in a pure form by recrystallization from a solution of chloroform and hexane and its detailed structure (Figure 3) was confirmed by X-ray analysis of a single crystal. The resonance of the methyl group of $2 a$ in ${ }^{1} \mathrm{H}$ NMR appeared at $\delta 0.68$, which is an upfield shift by 0.5 ppm from the ant $i$ isomer $\mathbf{2 b}$. This trend resembles that of complexes 1a and 1b, but thermal equilibration ( $K_{2}=1$ ) between 2a and 2 b in chloroform occurred more rapidly at room temperature (see kinetic part).

The reaction of $\mathrm{P}_{3}$ with $\mathrm{Mn}(\mathrm{CO})_{5} \mathrm{Br}$ also gave fac- $\left(\eta^{2}-\right.$ $\left.\mathrm{P}_{3}\right) \mathrm{Mn}(\mathrm{CO})_{3} \mathrm{Br}$ in a mixture of two stereoisomers 3a and 3b. The syn species 3a was separated from the mixture by recrystallization. The pure anti species was obtained from the photochemical substitution of $\left[\left(\eta^{3}-\mathrm{P}_{3}\right) \mathrm{Mn}(\mathrm{CO})_{3}\right]^{+}$ with bromide, reported by Ellerman and co-workers. ${ }^{10}$ The chemical shift of the methyl group in 3 a is upfield by 0.6

[^2]

Figure 1. ORTEP plot of 1a.

Figure 2. ORTEP plot of $\mathbf{1 b}$.
ppm from than that of $\mathbf{3 b}$, consistent with our observations of other complexes. The ${ }^{31}$ P NMR chemical shift of 3b appears at $\delta-27.76$ for an uncoordinating phosphine and at $\delta 29.39$ for coordinating ones, but for 3a at $\delta-26.94$ and $\delta 29.81$, respectively.

With the sulfur ligand $S_{3}$, the reaction produced ( $\eta^{2-}$ $\left.S, S^{\prime}-\mathrm{S}_{3}\right) \mathrm{Mn}(\mathrm{CO})_{3} \mathrm{Br}$ indicated by the infrared absorption of carbonyls and ${ }^{1} \mathrm{H}$ NMR. The attempted isolation of the desired complex by chromatography or crystallization led to decomposition with the recovery of free ligand $\mathrm{S}_{3}$. The coordination between manganese(I) and thioether appears relatively weak even with chelation.

All tripodal ligands act as bidentate with no indication of formation of ( $\eta^{3}$-tripodal) $\mathrm{Mn}(\mathrm{CO})_{2} \mathrm{Br}$ or [ $\left(\eta^{3}\right.$-tripodal)$\mathrm{Mn}(\mathrm{CO})_{3} \mathrm{JBr}$, even under reflux of $1 \mathrm{a}, 1 \mathrm{~b}, \mathbf{2 a}$, or 2 b in acetone solution. This property differs from that of ( $\eta^{2}$ $\left.\mathrm{P}_{3}\right) \mathrm{Mn}(\mathrm{CO})_{3} \mathrm{Br}$, which gave $\left[\left(\eta^{3}-\mathrm{P}_{3}\right) \mathrm{Mn}(\mathrm{CO})_{2}\right] \mathrm{Br}$ under reflux in polar solvents. Obviously, the weak coordination ability of thioether is responsible for this distinction.

All complexes ( $\eta^{2}$-tripodal) $\mathrm{Mn}(\mathrm{CO})_{3} \mathrm{Br}$ were characterized by spectral methods and elemental analysis. Infrared absorptions in the carbonyl region are consistent with facial tricarbonylmanganese complexes. The chemical shifts of the methyl groups in all cis isomers are upfield from those of the trans ones by about 0.6 ppm ; this difference becomes a unique way to identify these isomeric species. The protons of all methylene units in complexes 2 b are diastereotopic, as shown by the ${ }^{1} \mathrm{H}$ NMR splitting pattern. The structures of complexes $1 \mathbf{a}, 1 \mathrm{~b}$, and 2 a were further confirmed by X-ray analysis of single crystals.

Kinetic and Mechanistic Studies. By measuring the integration ratio of methyl groups between syn and anti isomers, we found that the isomerization of 1 a or 2 a to their corresponding anti species (eq 2) in $\mathrm{CDCl}_{3}$ under

$$
\begin{gather*}
\text { syn isomer } \underset{k_{-1}}{\stackrel{k_{1}}{\rightleftarrows}} \text { anti isomer } \\
K_{1}=2 / 3\left(\text { for complex 1), } K_{2}=1.0\right. \text { (for complex 2) }
\end{gather*}
$$

first-order conditions obeyed the rate law - d [syn isomer]/ $\mathrm{d} t=\left(k_{1}+k_{-1}\right)$ ([syn isomer] - [syn isomer] ${ }_{\infty}$ ). The rate constants of the isomerization at various temperatures for la and 2a are summarized in Table I. The activation parameters for isomerizations were obtained: $\Delta H^{*}{ }_{1 \mathrm{a}}=$ $30.5 \pm 0.4 \mathrm{kcal} / \mathrm{mol}, \Delta S^{*}{ }_{1 \mathrm{a}}=11 \pm 1$ eu for complex 1a; $\Delta H^{*}{ }_{2 \mathrm{a}}=24.9 \pm 0.7 \mathrm{kcal} / \mathrm{mol}, \Delta S^{*}{ }_{2 \mathrm{a}}=7 \pm 2 \mathrm{eu}$ for complex

2a. Based on the activation parameters, a proposed mechanism for this isomerization is shown in Scheme I. One donor in the tripodal ligands (phosphorus in 1a; sulfur in 2a) dissociates first to generate a pentavalent intermediate I, which is rapidly converted into another II, followed by recoordination of the donor atom. For 2a, the recoordinating of sulfur atom was either sulfur donor of

Scheme I. Mechanistic Pathway for Isomerization

$\mathrm{PS}_{2}$. Intermediates I and II might interconvert through an intermediate III. ${ }^{11}$ That the value of $\Delta H^{*}{ }_{2 \mathrm{a}}$ is smaller than $\Delta H^{*}{ }_{1 \mathrm{a}}$ reflects the weak coordinating ability of the sulfur atom to the metal and is consistent with the dissociation process as the rate determining step.
Structural Analyses. The data for crystals for complexes 1a, 1b, and 2a are summarized in Table II. ORTEP plots of 1a, 1b, and 2a are depicted in Figures $1-3$; the non-hydrogen atomic coordinates of these complexes are collected in Tables III-V, respectively. In all instances, the manganese metal displays a slightly distorted octahedral geometry with the two donor atoms of the tripodal ligand (two phosphorus atoms in $\mathrm{P}_{2} \mathrm{~S}$; one phosphorus and one sulfur in $\mathrm{PS}_{2}$ ) and bromide being in a facial arrangement. All bond distances and bond angles lie within normal ranges, ${ }^{12}$ illustrated in Table VI. The $\mathrm{Mn}-\mathrm{P}$ and $\mathrm{Mn}-\mathrm{S}$ bond lengths are essentially indistinguishable, except for M-P2 in 1a. The distances of Mn-C trans to bromide are slightly less than those trans to $\mathrm{Mn}-\mathrm{P}$ or $\mathrm{Mn}-\mathrm{S}$, as expected, because of the trans influences. ${ }^{13}$ For 2a, the metal-carbon bond trans to the phosphorus donor [ $\mathrm{Mn}-\mathrm{C} 8,1.81(2) \AA$ ] is slightly longer than that trans to sulfur [Mn-C7, 1.78(2) $\AA$ ], another consequence of the trans influence of donor atoms.
Examination of those dihedral angles along the chelate ring [Mn-P1-C1-C2-C3-Z] of cis complexes 1a and 2a (Table VII) reveals alternating +gauche/-gauche angles typical of a chairlike six-membered ring (Figure 4). That these angles deviate from the ideal $60^{\circ}$ of the cyclohexane ring presumably arises from the variation of the bond lengths within the chelate rings (e.g. M-P vs C-C). In order to retain a chair conformation, the congestion between diphenylphosphino moieties and the metal center causes distortion of P1-Mn-C6 from $90^{\circ}\left[102.1(3)^{\circ}\right.$ in 1a, $101.1(5)^{\circ}$ in 2a]. The bulky (phenylthio)methyl group is situated at an equatorial position in the six-membered chelate ring. The phenyl group of the coordinating thioether in 2a is positioned equatorially to avoid the unfavored diaxial interactions; such an arrangement also causes steric repulsion between this phenyl group and carbonyl C808, as indicated by the larger angle of S2-$\mathrm{Mn}-\mathrm{C} 8\left[97.7(6)^{\circ}\right]$. The angles of bromide to the plane

${ }^{a}$ Atoms with asterisks have occupance $=0.5$.
$\left(\eta^{2}-\mathrm{L}-\mathrm{L}\right) \mathrm{MnX}(\mathrm{CO})_{3}\left(\mathrm{~L}-\mathrm{L}=\mathrm{Me}_{2} \mathrm{AsCH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{AsMe}_{2}\right) ;{ }^{14}$ the particular configuration is possibly stabilized by an attractive interaction between the halide ligand and the axial hydrogens. ${ }^{14 \mathrm{c}}$
In contrast, a boat conformation of the six-membered chelate ring appears in $\mathbf{I b}$ (Figure 4), although the dihedral angles of $\mathrm{C} 1-\mathrm{C} 2-\mathrm{C} 3-\mathrm{P} 2\left[-9.7(3)^{\circ}\right]$ and $\mathrm{P} 2-\mathrm{Mn}-\mathrm{P} 1-\mathrm{C} 1$ [1.9(3) ${ }^{\circ}$ ] are not $0^{\circ}$ as for a typical boat form of the cyclohexane ring. The bulky group $\mathrm{CH}_{2} \mathrm{SPh}$ is situated at a pseudoequatorial position, whereas the methyl group has a pseudoaxial orientation. The bromide ligand is clearly pointed over the ring. As the stability difference between 1a and 1 b is $0.24 \mathrm{kcal} / \mathrm{mol}$ measured in solution, the adoption by 1 lb of a boat conformation is probably due to the crystal packing (see below).

Although X-ray analysis clearly gives the conformation of the chelate ring in the solid state, a remaining question is whether such a form is retained in solution. For fac$(\mathrm{CO})_{3} \mathrm{BrMnPPh}_{2} \mathrm{CH}_{2} \mathrm{C}(\mathrm{Me})_{2} \mathrm{CH}_{2} \mathrm{PPh}_{2}$ (4), Kraihanzel and

co-workers ${ }^{15}$ showed that the conformation of the chelate ring retained a stable chair form and the ${ }^{1} \mathrm{H}$ NMR shifts of axial and equatorial methyl groups appeared $\delta 0.30$ and 1.13 , respectively. Both the greater shielding ( $\delta 0.36$ ) of the methyl group of 1a and the similarity of the chemical shifts and the splitting pattern of methylenes attached to phosphorus atoms (compared to the axial one in 4) indicate that the conformation of the chelate ring of 1a in $\mathrm{CDCl}_{3}$ remains in a chair form with the methyl group positioned at an axial position. The same argument applied to 2a, which retains the chair form as in the solid state.
If the ring in $1 \mathbf{b}$ retains a boat form according to the configuration shown in Figure 5, then all protons of the methylene units would give a complicated ${ }^{1} \mathrm{H}$ NMR spectrum because all protons have different environments. Both the downfield shift of the methyl group ( $\delta 1.13$ ) and the splitting pattern in the ${ }^{1} \mathrm{H}$ spectrum, which are essentially similar to those in $4(\delta 1.13),{ }^{15}$ of the methylene groups attached to phosphorus atoms indicate that a chair conformation obtains for 1 b in $\mathrm{CDCl}_{3}$ solution. If 1 b were forced into a chair conformation, analogous to that of 1a, then the 1,3-diaxial interactions between $-\mathrm{CH}_{2} \mathrm{SPh}$ and the phenyl groups would be the only unfavorable factor for retention of such a conformation (Figure 5). Examination of a molecular model of la reveals the methyl group is rotation hindered because of steric interaction with the axial phenyl groups. Thus 1b ideally adapts a chair conformation with the phenylthio substituent pointing outward from the chelate ring, in order to minimize the unfavorable 1,3-diaxial interaction. The rotation about the carbon-carbon bond is also restricted for $\mathrm{C}-\mathrm{CH}_{2} \mathrm{SPh}$. According to these assumptions, the energy difference

1b

Figure 4. Another view of the crystal structure of 1 a and 1 b showing the chelate ring in the chair conformation for 1a and boat conformation for 1b (phenyl groups omitted for clear view).
between 1a and $1 \mathbf{b}$ in chair forms is expected to be relatively small, consistent with the measured value ( $\Delta G_{0}$ $=0.2 \mathrm{kcal} / \mathrm{mol}$ ) from the equilibration measurement.

## Summary

We investigated the coordination behavior of $\mathrm{P}-\mathrm{S}$ hybrid tripodal ligands toward manganese(I), in which all tripodal ligands act as bidentate to form fac-( $\eta^{2}$-tripodal) $\mathrm{Mn}(\mathrm{CO})_{3} \mathrm{Br}$. The weak metal-sulfur interaction, relative to metal-phosphorus, is illustrated quantitatively in the kinetics of isomerization. The stable chair conformations are preferred for the chelate rings in both solution and crystal structures, except that 1b has a boat form in the solid state. Further study of the formation of $\eta^{3}$-tripodal metal complexes and their properties is currently in progress.

## Experimental Section

General Information. Proton magnetic resonance spectra were recorded on either a Bruker AC-E 200 or a Bruker AM-

300WB spectrometer at room temperature. Proton-decoupled phosphorus-31 NMR spectra were determined on a Bruker AC-E 200 or a Bruker AM-300WB spectrometer at 81.01 or 121.49 MHz , respectively. Chemical shifts are given in parts per million relative to $85 \% \mathrm{H}_{3} \mathrm{PO}_{4}$ for ${ }^{31} \mathrm{P}$ NMR spectra in $\mathrm{CDCl}_{3}$, unless otherwise noted.
Infrared and UV/vis spectra were obtained on Perkin-Elmer 983G and Perkin-Elmer Lambda 3B instruments, respectively. Elemental analyses were made on a Perkin-Elmer 240C instrument.

All reactions, manipulations, and purification steps involving phosphines were performed under a dry nitrogen atmosphere. Air sensitive liquids were transferred by flexneedles using nitrogen pressure or by syringe. (CO) ${ }_{5} \mathrm{MnBr}$ was prepared according to the literature method. ${ }^{16}$ The tripodal ligands $\mathrm{P}_{2} \mathrm{~S}$ and $\mathrm{PS}_{2}$ were synthesized as described previously. ${ }^{5,6} P_{3}$ was obtained from Strem Chemicals; $S_{3}$ was prepared according to the literature procedure. ${ }^{17}$
syn- and anti-fac-Bromo $\boldsymbol{\eta}^{2}-P, P-2,2-B i s((d i p h e n y l p h o s-~$ phino)methyl)-1-(phenylthio) propane]tricarbonylmanganese(I), 1a and 1 lb . Into a flask were placed $\mathrm{P}_{2} \mathrm{~S}$ (44.4 $\mathrm{mg}, 0.081 \mathrm{mmol}$ ) and $\mathrm{Mn}(\mathrm{CO})_{5} \mathrm{Br}$ in $\mathrm{CHCl}_{3}$. The resulting mixture was heated at reflux for 2 h . Filtration and concentration of the reaction mixture gave the crude products ( $59.8 \mathrm{mg}, 96 \%$, the ratio of isomer 1a:1b $=6: 4$ ). Fractional recrystallization from dichloromethane and hexane gave isomer la as a yellow crystalline solid and isomer 1 lb as an orange-yellow solid.
Isomer la: mp 186-188 ${ }^{\circ} \mathrm{C} \mathrm{dec}$; UV/vis ( $\mathrm{CHCl}_{3}$ ) $389 \mathrm{~nm}(\epsilon=$ $\left.1078 \mathrm{~cm}^{-1} \mathrm{M}^{-1}\right), 246\left(\epsilon=1.25 \times 10^{4}\right)$; IR $\left(\mathrm{CHCl}_{3}\right) 2029,1961,1899$ $\mathrm{cm}^{-1}$; ${ }^{1} \mathrm{H}$ NMR $\delta 7.80-7.30(\mathrm{~m}, 25 \mathrm{H}), 3.47$ (dd, $J=14.4 \mathrm{~Hz}, J_{\mathrm{P}-\mathrm{C}-\mathrm{H}}$ $=6.6 \mathrm{~Hz}, 2 \mathrm{H}), 2.99(\mathrm{~s}, 2 \mathrm{H}), 2.31\left(\mathrm{dd}, J=14 \mathrm{~Hz}, J_{\mathrm{P}-\mathrm{C}-\mathrm{H}}=13 \mathrm{~Hz}\right.$, $2 \mathrm{H}), 0.36$ (s, 3 H ); ${ }^{31} \mathrm{P}$ NMR $\delta 30.52$. Anal. Calcd for $\mathrm{C}_{38} \mathrm{H}_{4} \mathrm{BrO}_{3} \mathrm{P}_{2} \mathrm{SMn}: \mathrm{C}, 59.46 ; \mathrm{H}, 4.28$. Found: C, $59.32 ; \mathrm{H}, 4.28$.
Isomer 1b: mp 174-177 ${ }^{\circ} \mathrm{C}$ dec; UV/vis $\left(\mathrm{CHCl}_{8}\right) 389 \mathrm{~nm}(\epsilon=$ $1078 \mathrm{~cm}^{-1} \mathrm{M}^{-1}$ ), $246\left(\epsilon=1.25 \times 10^{4}\right)$; $\mathrm{IR}\left(\mathrm{CHCl}_{3}\right) 2027,1960,1902$ $\mathrm{cm}^{-1}$; ${ }^{1} \mathrm{H}$ NMR $\delta$ 7.63-7.61 (m, 8 H ), 7.35-7.20 (m, 12 H ), 7.10$7.08(\mathrm{~m}, 3 \mathrm{H}), 6.62-6.59(\mathrm{~m}, 2 \mathrm{H}), 3.33\left(\mathrm{dd}, J=14 \mathrm{~Hz}, J_{\mathrm{P}-\mathrm{C}-\mathrm{H}}=\right.$ $7 \mathrm{~Hz}, 2 \mathrm{H}$ ), $2.55\left(\mathrm{dd}, J=14 \mathrm{~Hz}, J_{\mathrm{P}-\mathrm{C}_{-\mathrm{H}}}=7 \mathrm{~Hz}, 2 \mathrm{H}\right.$ ), $2.33(\mathrm{~s}, 2$ $\mathrm{H}), 1.13$ (s, 3 H ); ${ }^{31} \mathrm{P}$ NMR $\delta 30.52$. Anal. Caled for $\mathrm{C}_{38} \mathrm{H}_{34} \mathrm{BrO}_{3} \mathrm{P}_{2} \mathrm{SMn}$ : C, $59.46 ; \mathrm{H}, 4.28$. Found: C, $58.92 ; \mathrm{H}, 4.33$.
fac-Bromo [ $\eta^{2}$-P,S-2,2-bis((phenylthio)methyl)-1-(diphenylphosphino)propane]tricarbonylmanganese(I), 2a and 2b. These complexes were prepared similarly to 1 la and lb . Complex syn-2a was obtained as an orange solid by recrystallization from chloroform and hexane: mp 140-142 ${ }^{\circ} \mathrm{C}$ dec; IR ( $\mathrm{CHCl}_{3}$ ) 2036, 1967, $1914 \mathrm{~cm}^{-1}$; ${ }^{1} \mathrm{H}$ NMR $\delta 6.9-8.1(\mathrm{~m}, 20 \mathrm{H}), 4.39$ (d, $J=11 \mathrm{~Hz}, 1 \mathrm{H}$ ), $3.50\left(\mathrm{dd}, J_{\mathrm{H}-\mathrm{C}-\mathrm{H}}=13 \mathrm{~Hz}, J_{\mathrm{P}-\mathrm{C}-\mathrm{H}}=6 \mathrm{~Hz}, 1\right.$ $\mathrm{H}), 3.01(\mathrm{~s}, 2 \mathrm{H}), 2.58(\mathrm{~d}, J=11 \mathrm{~Hz}, 1 \mathrm{H}), 2.21\left(\mathrm{dd}, J_{\mathrm{H}-\mathrm{C}-\mathrm{H}}=13\right.$ $\left.\mathrm{Hz}, J_{\mathrm{P}-\mathrm{C}-\mathrm{H}}=16 \mathrm{~Hz}, 1 \mathrm{H}\right), 0.68(\mathrm{~s}, 3 \mathrm{H}) ;{ }^{31} \mathrm{P}$ NMR $\delta 27.0$.

Complex anti-2b was never obtained as a pure form but was identified by its spectral data: IR $\left(\mathrm{CHCl}_{3}\right) 2036,1967,1914 \mathrm{~cm}^{-1}$; ${ }^{1} \mathrm{H}$ NMR $\delta$ 6.9-8.1 (m, 20 H ), $4.33(\mathrm{~d}, J=12 \mathrm{~Hz}, 1 \mathrm{H}), 3.50(\mathrm{dd}$, $\left.J_{\mathrm{H}-\mathrm{C}-\mathrm{H}}=14 \mathrm{~Hz}, J_{\mathrm{P}-\mathrm{C}-\mathrm{H}}=6.5 \mathrm{~Hz}, 1 \mathrm{H}\right), 2.99(\mathrm{~d}, J=12.8 \mathrm{~Hz}, 1 \mathrm{H})$, $2.79(\mathrm{~d}, J=12 \mathrm{~Hz}, 1 \mathrm{H}), 2.40\left(\mathrm{dd}, J_{\mathrm{H}-\mathrm{C}-\mathrm{H}}=15 \mathrm{~Hz}, J_{\mathrm{P}-\mathrm{C}-\mathrm{H}}=15\right.$ $\mathrm{Hz}, 1 \mathrm{H}), 2.31(\mathrm{~d}, J=12.8 \mathrm{~Hz}, 1 \mathrm{H}), 1.22(\mathrm{~s}, 3 \mathrm{H})$; ${ }^{31} \mathrm{P}$ NMR $\delta 25.8$. Anal. Calcd for $\mathrm{C}_{32} \mathrm{H}_{29} \mathrm{BrO}_{3} \mathrm{PS}_{2} \mathrm{Mn}$ : C, 59.46; H, 4.28. Found: C, 58.92; H, 4.33.
fac-Bromo[P,P-2,2-bis((diphenylphosphino)methyl)-1(diphenylphosphino)propane]tricarbonylmanganese(I), 3a and 3 b . These complexes were prepared by a method similar to that described for 1a and 1b. The separation of these two stereoisomers was not achieved. Both complexes have the same infrared absorptions in the carbonyl region, 2029, 1961, and 1902 $\mathrm{cm}^{-1}$. These two species were identified according to the ${ }^{1} \mathrm{H}$ NMR and ${ }^{31} \mathrm{P}$ NMR spectra.

3a: ${ }^{1} \mathrm{H}$ NMR $6.9-7.8(\mathrm{~m}, 30 \mathrm{H}), 3.43(\mathrm{dm}, J=15 \mathrm{~Hz}, 2 \mathrm{H})$, $2.34-2.30(\mathrm{~m}, 2 \mathrm{H}), 2.31(\mathrm{~s}, 2 \mathrm{H}), 0.38(\mathrm{~s}, 3 \mathrm{H}) ;{ }^{31} \mathrm{P}$ NMR $\delta-26.94$ (s), 29.81 (s).

[^6]
(A)

(B)

Figure 5. Comparison of the chelate rings of both la and $\mathbf{1 b}$ in chair forms.

3b: ${ }^{10}{ }^{1} \mathrm{H}$ NMR 6.9-7.8 (m, 30 H ) $3.31(\mathrm{dm}, J=15 \mathrm{~Hz}, 2 \mathrm{H})$, 2.48-2.61 (m, 2 H ), 1.82 ( $\mathrm{s}, 2 \mathrm{H}$ ), 0.99 (s, 3 H ); ${ }^{31} \mathrm{P}$ NMR $\delta-27.76$, 29.39.

Kinetic Experiments. On the basis of ${ }^{1} \mathrm{H}$ NMR spectra, because the chemical shifts of the methyl groups in syn- and anti- isomers differ significantly, the measurement of the concentrations of the two species was achieved by means of the integration of these peaks. Either la or 2 a was frozen in a 5 -mm tube at $-30^{\circ} \mathrm{C}$; deuterated solvent was added. The NMR tube was transferred to the ${ }^{1} \mathrm{H}$ NMR spectrometer. The reaction temperature (i.e. the temperature of the probe) was controlled by the instrument itself and was calibrated according to a method described by Van Geet. ${ }^{18}$ The appearance of either 1 lb or $\mathbf{2 b}$ and the disappearance of either la or 2a with time were followed by monitoring the peaks of the methyl groups. All reactions reached equilibrium; the concentration of the syn isomer was used as the [syn isomer]. value. The first-order rate constants were deter-

[^7]mined from a plot of $\ln \left(X_{0}-X_{\mathrm{m}}\right) /\left(X-X_{\omega}\right)$ vs time using a standard linear-squares treatment, $\mathrm{X}=$ molar fraction of syn isomer.

Crystallography. Cell parameters were determined on a CAD-4 diffractometer at 298 K by a least-squares treatment. Atomic scattering factors were taken from ref 19. Calculations were performed by using the NRCC SDP VAX package. ${ }^{20}$ The crystal data of 1a, 1b, and 2a are listed in Table II, and their non-hydrogen atomic coordinates are listed in Tables III-V, respectively. Other crystallographic data are collected as supplementary materials.

Acknowledgement. Financial support from the National Science Council, Taipei, Taiwan, Republic of China (NSC81-0208-M002-44), is acknowledged.

Supplementary Material Available: Tables listing complete bond distances, bond angles, and anisotropic thermal parameters for $1 \mathbf{a}, 1 \mathbf{b}$, and 2 a ( 12 pages). Ordering information is given on any current masthead page.
